The many problems concerned with the period of study — fatigue, the best alternation of periods of work and rest, the length of the school day, one session or two, recesses, pauses, etc. — have all been made the subject of scientific investigation. The importance of this newer field of school hygiene is seen when one considers the fact that an important means of curing nervous and mental disorder is re-education, the development of healthful habits of mental activity — wholesome interests, habits of attention, self-control, and orderly association — in fact, the very habits that are essential for hygienic school work. And when one further reflects that the inmates of such institutions were a few years ago pupils in the public schools, the advantage of developing such habits as prophylactic against nervous and mental breakdown is obvious. More and more scientific investigation and observation are showing the hygienic importance of such mental training; and the hygiene of instruction has become of vital significance to the teacher.

**The Construction, Equipment, and Sanitation of the Schoolhouse.**—First of all the sanitary surroundings of the schoolhouse have been made the subject of investigation. The schoolroom is a workshop. The conditions must be made hygienic for the work to be done in it. The work required is performed chiefly by the brain, by the eye, and ear, and by the hand under the control of the eye and the brain. Thus the conditions necessary are not merely the avoidance of whatever would be injurious,—a stagnant, poisonous, arid, or overheated atmosphere, too intense light, glare from surrounding buildings, noisy occupations, unsuitable rooms, etc., but in every way the optimum conditions for such work—especially abundant and properly regulated light and an ample supply of oxygen. So important is the condition last mentioned both for the health of the pupils and the work to be done that the desirability of schools out of doors, or in conditions approximating those out of doors, is now being emphasized. Since in most parts of the country, however, a large amount of indoor work seems necessary on account of inclement weather, it is becoming more and more important to provide hygienic conditions in the schoolroom.

Thus this department of school hygiene is concerned first of all with the optimum conditions for a workshop where the laborers are growing children and the labor brain work. Architectural and artistic considerations are important, but secondary. First of all must be considered the health of the workers. For example, the unit in a schoolhouse is the schoolroom, and the size of the room should be determined by consideration of the average limits of normal sight and hearing, and the problem of construction is that of grouping a sufficient number of such units in a schoolhouse in a convenient way to give suitable light, air, etc. Many scientific studies have been made of the best forms of construction, and of methods of heating, ventilation, lighting, etc., and from these and the experience in building millions of schoolhouses certain definite norms for construction have been established. If we could bring together into one schoolhouse all the good features that are actually incorporated in various schoolhouses throughout the country, features which actual experience has shown to be of practical utility, we should have a model schoolhouse. Most schoolhouses, however, are seriously defective in certain aspects, and some apparently ignore modern hygiene altogether.

**HYGIENE, SOCIAL**—See SEX HYGIENE

**HYGIENE, TEACHING OF**—The importance of the teaching of hygiene can hardly be overestimated. Health represents a universal human interest. Its importance can be estimated only in terms of human value. Efficiency, to adopt the modern slogan, is impossible without it. Both directly as contributing to personal well-being and indirectly as contributing to the welfare of others, health is a prime condition of human happiness and even of morality. Such truths, which are so commonplace as to be merely platitudes, should not only be taught to the young, but should be made vital by training. Hence the aim of education from the point of view of hygiene is the development of habits of healthful activity both physical and mental. This training in habits of health should be supplemented by suitable instruction at different grades. To insure such training and such instruction, an adequate course in hygiene and proper training are imperative in the preparation of all teachers. This is the consensus of hygienists, and a resolution to emphasize this need was passed by the Second International Congress of School Hygiene at London, 1907.

**Instruction in Hygiene in the Schools**—The extent to which instruction in the prin-

ciples and practice of hygiene has been introduced into the schools of the United States is indicated by the recent investigations of the American School Hygiene Association. Meylan reported on 116 colleges, of which 75 per cent were giving instruction in hygiene. Twenty-six per cent of the colleges reporting on the details of their work were giving instruction in personal hygiene only; 24 per cent were giving instruction in general hygiene; others reported in smaller percentages that instruction is being given in emergencies, community hygiene, industrial hygiene, and mental hygiene. Seventy-nine per cent of these colleges reported that students were required to undergo a medical examination before taking up their work. Seventy-nine per cent reported regular sanitary inspections of school buildings and dormitories; 77 per cent inspected kitchens; 83 per cent inspected the water supply and grounds. Twenty per cent of these colleges accepted hygiene as a credit for admission.

Gulick reported on 90 public normal schools and on 2392 public high schools. Seventy-four per cent of the normal schools and 16 per cent of the high schools were giving instruction in hygiene. At the last Congress of the American School Hygiene Association, Gulick reported on 758 cities having graded public school systems. He found that 45 per cent of those cities "have regular organized systems of medical inspection in their schools" and "about one quarter of the cities have systems under the Board of Health" and three quarters are under the Board of Education. "Only a little more than one half of them undertake physical examinations." Seventy-six of those cities were employing school nurses, and forty-eight, school dentists. (See MEDICAL INSPECTION.) Twenty-five per cent of those cities were using individual drinking cups, and 75 per cent had sanitary drinking fountains. (In some of the cities both systems were in use.) "Over one half of these schools use moist cloths for dusting, in nearly all of them dust-absorbing compounds are used in sweeping; and in nearly a tenth of them the schools are supplied with vacuum cleaners." Most of these cities reported that their schoolroom floors were washed once in a month or once in three months, "although it is by no means rare to find cities in which they are washed once in five months or never washed at all." Adjustable desks are reported in about one half of the cities heard from. "Ninety-five per cent of the cities teach their children the effects of alcohol and tobacco; 61 per cent have special courses on the prevention and cure of tuberculosis, and 48 per cent give lessons in first aid." It is very evident from these reports that a large number of the larger cities in the United States have made provision for instruction in the principles of hygiene and have organized systems of medical and hygienic supervision which must be more or less effective in establishing the practice of hygiene.

Europe, Canada, Australia, New Zealand, Japan, China, Mexico, and Argentina are reported as having plans for various improvements in school hygiene. Medical inspection, school nurses, open air schools, school lunches, school dental clinics are being reported from the larger cities all over the world. On the other hand, little is being said about the introduction of hygiene into the curricula of the schools. It is difficult to introduce a new subject into the school curriculum. School curricula everywhere are already overcrowded, and it has been difficult to secure time and opportunity for the instruction of pupils in the principles and practice of hygiene in the primary and secondary schools. France has provided some instruction in her primary schools. The teacher gives this very elementary instruction as a minor part of his regular work. The higher schools have more advanced instruction given by the teacher or professor of natural history. The English Parliament (May, 1911), considered a bill "to require that in public elementary schools instruction shall be given in hygiene and to girls in the care and feeding of infants," and the Education Board issued syllabuses on these subjects. The status of instruction in hygiene in the secondary schools of the British Isles was stated by C. E. Shelly at the International Congress on School Hygiene, London, 1907 (see *Proceedings*, p. 919) as follows: "It cannot be said that hygiene has any existence as a recognized subject of instruction in the Secondary Schools of this country with the exception of a certain number of training schools for teachers." No instruction in hygiene is required by law in Russia. The instruction that is given is given voluntarily, and is optional. The same condition is general throughout Europe. Attempts have been made in Germany to provide school instruction in sex hygiene (*q.v.*). At last reports the authorities repressed the effort. Austria is at present giving such instruction in connection with anatomy to pupils in the preparatory schools. This plan has been in operation three years. It is reported that recently this instruction has been extended to the lower Austrian schools so that pupils who leave at the age of fourteen years will have had its benefit.

**Scope of a Course in Hygiene.**—Authorities differ as to the proper content of a course in the principles of hygiene. The older texts combined a study of anatomy and physiology with a study of the influences that act injuriously upon the organs and therefore upon their physiological activities. Some of the later texts minimize the amount of anatomy and physiology presented and emphasize the presentation of more purely hygienic material.

Leaving out of consideration the essential value of an intelligent knowledge of the main facts of human anatomy and physiology, there remain obviously very strong reasons why an intelligent knowledge of hygiene is impossible

without an equally intelligent knowledge of anatomy and physiology. The teacher must be well informed in these fundamentals, for he cannot afford to be ignorant of the basis of his subject. The pupil must necessarily be content to take many things for granted, but his hygienic education will be more valuable in the proportion in which it is based on a real knowledge of its scientific basis. The amount of time necessary to give an adequate knowledge of physiology and anatomy will depend on whether or not physiology is taught elsewhere in the curriculum as well as on the age of the pupil and on the phase of hygiene under consideration.

There are different points of view also concerning the content of elementary, intermediate, and advanced courses in their relation to each other. A common plan is to consider the same subject matter year after year, going more deeply into the details each time. The opposing plan is to take up new phases of hygiene each term, utilizing at the same time the facts already presented. Another variation in the conception of the proper content of a course in hygiene is that which includes procedures calculated to develop the practice of hygiene. Habit is most important. We must have the knowledge, but the knowledge is of little use if it is not applied in the daily habits of the individual. The procedures that tend to develop habits of hygiene are physical exercise (games, sports, plays), swimming bathing, tooth-brush drills, hygienic and medical inspection with the correction of bad habits of hygiene and of remediable incapacitating physical defects, routine exclusions for contagious cases and cases exposed to contagious disease. This conception combines instruction in the principles of hygiene with instruction in the practices of hygiene. It unites classroom instruction with the applications of hygiene in the various departments and divisions of the school.

It is most desirable from the standpoint of educational method and effective results to combine the essentials of related anatomy and physiology with a carefully graded sequence of hygienic subjects, at the same time insisting on the practice of health habits and procedures from those of simple cleanliness and exercise up to those of individual relief from the handicap of physical defect and those of community protection against communicable disease.

**Methods of Instruction in Hygiene.** — There is the same necessity for sound educational methods in presenting the subject of hygiene to school children or college students as there is in the presentation of any other subject taught them. The object of this instruction in hygiene is the establishment of right habits of living based upon a rational knowledge of the reasons why those habits are right. The subject is essentially scientific in its foundations and logical in its application. All the arguments that have been advanced in support of

better educational methods of teaching scientific subjects and all the arguments that have been advanced in support of educational methods that will best develop the power of reasoning are arguments in favor of the employment of the best educational methods in the teaching of hygiene. The subjects which are basal to hygiene, such as physiology, anatomy, and bacteriology, should be taught by the methods that have been found most effective for those subjects. The need for dissections, models, illustrations, diagrams, charts, specimens gross and histologic, and clay molding in anatomy; of illustrations, references, laboratory experiments, and so on in physiology, of cultures, experiments, and specimens in bacteriology is as important when these subjects are a part of a course in hygiene as they are when they are independent.

The curricula of our schools are already overcrowded. The addition of hygiene as a complete subject means a large addition. For these reasons there are very few schools in which hygiene is presented in anything like its complete form. The commonest school method is that which utilizes a selected textbook from which the pupils prepare their recitations. Charts, diagrams, illustrations, and practical questions accompany the recitations. Where departments of biology exist, or where physiology or bacteriology is taught, these subjects are often made to cover hygiene or various parts of it. Many of our high schools and colleges are placing hygiene in the Department of Physical Education, where it has a peculiar appropriateness. A good deal of hygiene is taught by the medical inspectors and nurses in some of those schools that have an efficient system of medical inspection.

**Teaching of Hygiene in the Primary Grades.** — The young child on entering school brings with him the habits of hygiene which have been taught him at home. If his mother has taught him good habits of eating, good habits of excretion, good habits of bathing, good habits of exercise, and good habits of rest, the problem of his hygienic instruction during his elementary years in school is much simplified. In fact he has already received a quality of instruction which from the standpoint of his physiological well-being and efficiency will never be surpassed at any other time in his life. As a rule, however, the young child on entering school, particularly the city child, is in need of more or less forceful instruction in the habits of hygiene, and has a faulty knowledge of even the simpler principles of hygiene. The individual need for and the character of instruction must be determined by the teacher or authorities in charge. It is obvious that such matters as cleanliness of the body and wearing apparel, care of the teeth, eyes, ears, nose, hair, and nails, habits of play, excretion, and posture, will figure prominently in this early instruction. The teacher will have profitable recourse to informal talks,

personal talks, and the use of simple charts, pictures, diagrams. There should be hygienic and medical examinations supported by a requirement that reasonable hygienic and medical advice must be respected. This combined instruction in principles and practices of hygiene will tend even at a very early age to establish principles and practices in the thoughts and acts of the child.

**The Teaching of Hygiene in the Grades and in the High School** — Throughout the later work in the grades and in the high school there should be the same careful correlation between the instruction in the principles of hygiene on the one hand and the procedures and conditions of applied hygiene and sanitation on the other hand as they exist in the school system, its buildings, grounds, and material equipment. The educational influences from these various sources should be harmonious. There should be no inconsistencies between general scientific hygienic principle and local hygienic practice. The subject matter in any given course in hygiene should include particularly the hygienic features connected with the health problems which occur in the daily lives of the individuals concerned. Such a course would logically include the following topics: Food, its physiological importance and requirements; its source, its contaminations, its preparation, its ingestion, the influences of emotional states on its digestion, its assimilation and its excretion. Water, its physiological importance; its contamination. Air, its physiological importance, its contaminations, its alterations under various meteorological conditions, ventilation. The excretions, their physiological significance; care of the bowels, the kidneys, the skin, the lungs. Physical exercise, its importance, its necessity, its varieties; its abuse. Rest; mental and physical rest, relative rest and recreation, sleep. The influence of abnormal conditions on health, *e.g.* defective vision, obstructed breathing, adenoids, tonsils, defective and unclean teeth, diseased gums, sluggish ulcers, wounds and old areas of irritation, exposures to heat, to cold, to moisture and to drafts, fatigue. The effects of bad habits on health; *e.g.* rapid eating, mouth breathing; unwise use of the eyes, sex habits, the abuse of tea, coffee, alcohol and tobacco, opium and cocaine habits. The causes of disease, such as pathogenic bacteria and other parasites. The carriers of disease, such as the fly, the mosquito, the flea, the rat, and careless human beings. Our defenses against disease, such as fresh air, sunshine, cleanliness, and good health. Special hygiene, such as domestic hygiene, municipal hygiene, community hygiene, industrial hygiene, school hygiene, "sex hygiene." First aid to the injured, and the care and feeding of infants.

**Legal Requirements.** — In most city school systems special emphasis is laid on the unhygienic influences of alcohol and tobacco. A

number of state legislatures have enacted laws requiring such instruction in the schools of the state. The importance of this instruction is great. No course in hygiene can be complete without including a discussion of alcohol and tobacco. There is, however, a question as to the wisdom of specifying through state law that these subjects be included unless the law is made to cover in addition other equally important subjects such as dental hygiene, the hygiene of alimentation, pathogenic bacteria, the fly and the mosquito as carriers of disease, spitting, and so on. Emphasizing the importance of instruction concerning the unhygienic effects of alcohol and tobacco through legal procedure must inevitably make other seriously important phases of hygiene seem to be a matter of secondary consideration. See ALCOHOL; TEMPERANCE, INSTRUCTION IN.

**Instruction in the Training School for Teachers** — The hygiene taught in the training school for teachers should include instruction in anatomy, physiology, bacteriology, and certain phases of sociology. Special emphasis should be placed on the instruction in school hygiene, domestic hygiene, municipal and community hygiene, industrial hygiene, and certain of the general features of military hygiene and sanitation. In addition to the special topics noted in this paper for instruction in the grades and high school, the normal school should cover the following topics in school hygiene: the school site, buildings, and playgrounds, the material equipment, including benches, blackboards, lighting, ventilation, heat, water, toilets, accommodations for exercise, rest, and eating; school supplies, such as pencils, books, chalk, apparatus and utensils; the standardization of schoolbooks, systems of cleaning, such as moist wiping, special sweeping, vacuum cleaning, periodical and special fumigation, and antiseptic cleaning; the food, dress, weight, and morbidity of school children, the fatigue of school children; infectious diseases and school epidemics, the ears, eyes, noses, throats, teeth, and mouths of school children, nervous conditions, cripples, defectives, and the morbid and criminally inclined. T. A. S.

**HYPÆSTHESIA, or HYPOÆSTHESIA** — The decrease in ability to appreciate stimuli. The term is applicable to all forms of sensation, including vision, hearing, taste and smell, as well as touch, pressure, and pain, but is commonly applied only to the latter group of sensations. Since special words are employed to describe the decreased ability in vision, in hearing, in smell, in taste, in temperature sensations, and in pain, it is customary and the best usage (although the custom is not always adhered to) to restrict the use of the simple terms ending in *-æsthesia* (*i e* an-, hyper-, and hypo-*æsthesia*) to the pressure-like sensations such as those of touch and pressure. S. I. F.

See ANALGESIA, ANÆSTHESIA, HYPERÆSTHESIA

**HYPALGESIA, or HYPOALGESIA** — The decreased ability to appreciate painful stimuli. See ANALGESIA, ANÆSTHESIA

**HYPATIA OF ALEXANDRIA** — One of the most eminent women teachers of antiquity, and one of the ablest of the later Greeks. In spite of her remarkable position and the somber tragedy of her death, few passages relating to her survive, but they uniformly ascribe to her an exceptional distinction for culture and influence no less than beauty and virtue. She was probably born between 360 and 370. Suidas says that she flourished under Arcadius (395-408), Philostorgius places her story in the reign of Valens (364-378); and John Malalas describes her as an "aged woman" at the time of her death (416). Her father, Theon, was a distinguished teacher of astronomy and mathematics at the Museum. Two of his many works still survive. But the daughter, Suidas says, surpassed her father in ability, and went on from mathematics to philosophy. She wore the philosopher's cloak, and expounded Plato, Aristotle, and "the other philosophers" (probably Neoplatonist) to large bodies of students. The statement that she taught on the street seems to be a misinterpretation. The article in the *Lexicon* of Suidas is a late and adulterated epitome of an earlier writer, but the letters of Bishop Synesius, an enthusiastic pupil, and the *Ecclesiastical History* of Socrates confirm her position. Socrates says that she "surpassed all the philosophers of the time, and taught in the Platonist (Neoplaton-

ist) school founded by Plotinus." The Neoplatonist school had by that time been detached from the Museum, and its one woman teacher drew pupils from all parts of the Greek world. Hierocles, Synesius, Troilus, and other known scholars were amongst her pupils. Her chief distinction was in philosophy, but she imparted "all disciplines," — mathematics, mechanics, astronomy, and philosophy, — and the letters of Synesius refer to her technical skill. Two large works are mentioned as having been written by her, but they have not survived: an arithmetical *Commentary on Diophantus* and a *Commentary on the Conic Sections of Apollonius of Perga*. She is described as a fluent, precise, and attractive speaker, and is uniformly praised for beauty and high character. Suidas tells that the leading persons of the city used to visit her, as it was the custom at Athens for magistrates to visit distinguished teachers. Socrates narrates that she was friendly with Orestes, the Prefect, and that this friendship led to her lamentable fate. A mob seized her as she entered her litter, dragged her through the streets, and, after tearing her flesh from her bones with oyster shells or broken pottery, burned her remains. The cause is obscure, but Socrates seems to suggest that the Archbishop Cyril's followers laid the blame for the friction that existed between the Prefect and Cyril on the aged and influential pagan teacher. The murder was perpetrated in 416, when Hypatia must have been in or beyond the sixth decade of her life. She is the heroine of Charles Kingsley's *Hypatia*. J. M.

**HYPER** — A prefix to indicate an exaggerated degree of any characteristic. Thus hyper-*æsthesia* is an excessive degree of sensitivity.

**HYPERÆSTHESIA.** — An increased sensitivity to stimuli in any sensory field, but usually applied to the abnormal sensibility of the skin and the underlying tissues. The hyper-*æsthesia* may be of peripheral or central origin, due to abnormalities in the sensory end organs or in the spinal cord or brain, respectively. Certain substances applied to the skin produce a peripheral hypersensitiveness which is probably due in large part to the increased blood supply. Examples of this are the conditions following the application of very hot, not burning, stupefies, of mustard plasters, of turpentine and of cantharides to the skin to act as "counter irritants." All of these leave the skin hypersensitive, at times so much so that the individual cannot bear the pressure of his clothing. Pedagogically the hyper-*æsthesia* are of little importance, except that in a highly

## HYPERALGESIA

nervous individual of unstable mental make-up they may lead to convulsions, to voluntary isolation, etc

S I F

See ANÆSTHESIA, ANALGESIA, and the references there given

**HYPERALGESIA** — The exaggeration of the pain sense, whereby (1) pain-producing stimuli are felt to be more painful than normally, and (2) the pain threshold is lowered and stimuli which do not produce pain in a normal individual or in normal parts give rise to pain sensations. Sections of the body with a lowered pain threshold are sometimes called "tender areas."

See ANÆSTHESIA, HYPÆSTHESIA; HYPERÆSTHESIA  
S I F.

**HYPERMETROPIA** — See EYE, especially Sections on Hygiene of the Eye and Tests of Vision

**HYPEROPIA** — (ὕπερ, over, and ὤψ, eye). That condition of refraction where the eyeball is too shallow, and hence parallel rays of light come to a focus behind the retina. The hyperopic eye is an undeveloped eye. It is, in fact, the normal condition of the human eye in infancy. Even with children of school age some investigators have found the majority of children with hyperopic eyes, but the number of such eyes decreases with the increased age and higher grade of the pupils, although the defect remains permanent in a considerable percentage of cases. While it is the normal condition for young children, the fact of this prevalence of hyperopia makes certain hygienic precautions necessary. In the first place the undeveloped eye of childhood, the hyperopic eye, is better fitted for looking at objects at a distance than for near work. Reading, for example, is an occupation peculiarly ill fitted for the hyperopic eyes of children, for their arms are too short to hold a book conveniently even at the normal distance of twelve inches, while a greater distance would be desirable for them. The error of refraction can be overcome by accommodation, but the child with hyperopic eyes reads with great muscular strain. This defect, especially when combined, as frequently happens, with astigmatism, often causes headache and other physical disorders.

When the hyperopia amounts to two diopters, or in any case on the advice of a competent oculist, the error of refraction should be corrected by the use of convex lenses. The fact of hyperopia as the normal condition of the eye in infancy, the changing degree of refraction as the eye develops, and the need of adaptation to the actual condition at each stage, illustrate the importance of yearly tests of children's vision and of expert advice when marked changes occur.

## HYPNOSIS

**HYPNOSIS** — The phenomena of the hypnotic state are induced through a psychological alteration of consciousness and control, which in turn are presumably conditioned by a change of status of brain-functioning. Though plausible theories have been offered in explanation of the susceptibility to assume the hypnotic state, it cannot be said that we understand its nature, nor just what happens in the nervous system when hypnosis ensues. Psychologically we find in hypnosis a handicapped or impaired functioning, the loss of relation to the environment, to the normal assimilation of experience as material for the personal memory-continuum, and to the normal initiative and direction of the mind's concerns. The losses thus entailed lay the hypnotized subject open to the direct suggestion or command of messages and influences that reach his altered consciousness; so that exaggerated suggestibility comes to be the most conspicuous symptom of the state. That other handicapped states offer analogous relations is set forth under the term "suggestion" (*qv*). Through the large areas of excluded mental action and responsiveness there goes out to the impressions that enter an intensive concentration, which again conspicuously characterizes the phenomena of this state. In this respect the analogy of the state to somnambulism as it spontaneously occurs in predisposed individuals is very close, and gave to the state the name of artificial somnambulism.

The typical phenomena may be briefly summarized. The state is induced by the consent of the subject who passively yields to the request to seek sleep, to yield the command of his thoughts and to relax. A sharp command (partly reinforced by strokings or similar manipulations), such, for example, that he cannot open his eyes, may then be successful, and the attempt to open the eyes fail or succeed only after repeated trials. The anticipation of the altered condition being thus gradually established, it is entered upon by trained subjects in response to any sign or suggestion, and similarly a snap of the fingers, an upward stroke, a sharp call in an altered tone, breaks up the state, and restores the subject to the normal condition. The development of the symptoms proceeds rapidly and through suggestion. The subject becomes responsive only to the presence and word of the operator. He sees and hears nothing that is not presented to his avenues of sense by such imposed suggestion. He will regard the fountain-pen as a stiletto, and the upholstered chair as his victim. He will see a blank card as a photograph; and he will fail to see objects really present which he has been informed are spirited away (negative hallucination). He will perform actions seemingly impossible to his normal powers of self-command; and hysterical subjects — the hysterical state either emphasizing or complicating the hypnotic disposition — will show mental in-

## HYPNOSIS

fluence over functions (such as the healing of scars) physiologically removed from conscious influence. Though obviously endless in variety, the hypnotic phenomena present but the developments of suggestibility, made possible by the limitations of responsiveness and the surrender of directive control. Similarly, the actions of the (deeper) hypnosis remain unrecalled to the waking consciousness and find no place in its memory sequence. But here the psychic impairment becomes more subtle and exhibits the typical relations of the subconscious phenomena. For it may be shown that what is thus excluded from the normal consciousness is not wholly excluded, and by indirect and circumventing devices may be shown to find some sort of registry. Likewise the hallucinations and the insensibilities of the hypnotic state are not wholly complete; and what the hypnotic consciousness fails to perceive yet finds indirect record. (See SUBCONSCIOUS.) The situation becomes yet more complex through the possibility of post-hypnotic suggestion, for here the suggestion, though imposed in hypnosis, is yet acted out in the normal condition. The subject realizes his action, gives some excuse for it, if it is foolish or improper, and accepts it as his own conduct, due to an impulse for which he cannot quite account.

The applications of hypnotic suggestion for the curative treatment of disease, particularly of nervous functional troubles, has the same basis as that of waking suggestion, but through the artificially induced state lowers the resistance which a more nearly waking consciousness might, in spite of a consenting effort, obstructively exercise. Questions of legal responsibility and commission of crimes in the hypnotic state have also led to critical discussions, and have raised the question as to whether the subject does not recognize the sham character of the crime which he hypnotically commits. Yet the practical submission of the subject to the operator's will has led to a more cautious use of the process, and affects the bearing of its practical applications.

Historically the state is connected with the older theories of an actual physical influence streaming from the operator's person and physically affecting the subject, and again to the theories of special sensitiveness of the subjects by virtue of which they developed powers beyond the normal. The former comes directly from Mesmer and the doctrine of animal magnetism, or an all-pervasive magnetic influence which the favored operator embodies in his own person; the latter found its development in the notion of "sensitives" or "mediums" later absorbed by the spiritualistic sense of the term. It was the outgrowth of these unsupported notions and the explanation of the phenomena on the basis of an altered physiological and psychological state that was the special contribution of James Braid (1795-

## HYPOTHESIS

1860), and which inaugurated the modern study of the topic. (See MESMERISM.) J. J.

### HYPNOTISM — See HYPNOSIS

**HYPOTHESIS** — A supposition, a theory, or a mode of explanation held tentatively pending further inquiry, because of its value in the organization of knowledge and in direction of inquiry. The increased importance attached, in the development of modern science, to making and using hypotheses is a necessary part of the evolution of inductive and experimental science. It marks the attainment of a genuinely critical reflective attitude, and provides the working method for dealing with the otherwise insoluble antagonism of dogmatism and skepticism. The older and classic scientific attitude (commonly called deductive, but better termed subsumptive or authoritative) assumed that science was possible only where there existed a body of absolutely certain and definite fixed principles of "truths," under which empirical or observable data might be brought. Only as the body of experienced data was subsumed under the absolute first principles did the former acquire logical systematization and rational justification, that is, the characteristic traits of a science. These first principles were themselves, accordingly, of a radically different nature from that of the facts of experience. The former were universal and necessary, self-evident truths of reasons or rational intuitions, innate ideas, *a priori* to all experience. The latter were *a posteriori*, the result of sensations and imagination, contingent, fluctuating, particular. When acceptance of ultimate rational principles was made the foundation of all science, doubt and denial of their existence led to skepticism regarding the possibility of knowledge. Dogmatism and skepticism thus exhausted the philosophies of knowledge.

The modern scientific movement began when men gave up the notion that science consisted in defining and classifying existences just as they were found and substituted the search for processes and energies which made the objects, or brought them into existence. The latter point of view necessarily involved the use of imaginative conceptions of *possible* causes. The speculative danger latent in the new method was checked by insistence that the imaginative conceptions, or hypotheses, must lend themselves to mathematical statement, deduction, and to corroboration by the results of

experimental observations. Descartes' theory of knowledge marks the transition from the older to the newer, or scientific, logic. He retained the notion that science begins with truths or concepts of pure reason, and that what was needed was concentric deduction from these universals, until the phenomena revealed to sense observation were approximated. At the same time he insisted upon the necessity of definite and accurate (mathematical) formulation of these ultimate notions and upon methodic procedure, a series of intermediate steps from the universal to the particulars. When the Cartesians called these ultimate principles "hypotheses," they did not mean to imply their doubtful character, but rather that they were "placed under" all the particular facts of existence and of science. When Newton said that he did not make hypotheses (*non fingo hypotheses*), he did not mean (as is sometimes stated) that he did not gratuitously invent them, but that he did not employ them in the Cartesian way. In the modern sense, no one invented or used hypotheses more freely than Newton, but, as against the Cartesian theory of the world, he held that general interpreting principles must not be derived from pure thought, but be suggested by experience and then transferred by analogy to other phenomena, their verification existing in the suggestion of new or experimental observations exactly confirming the deductive results. In Kant, we find again an inconsistent compromise of the old and the new logics. He recognizes that science does not consist in the mere accumulation and classification of facts, since it requires conceptions which the mind, from its own initiative, uses to cross-examine existing observations and employs also as methods of undertaking new experimental constructions. To quote his own words: "When Galileo caused balls which he had carefully weighed to roll down an inclined plane, or Torricelli made the air bear up a weight which he knew beforehand to be equal to a standard column of water, a new light broke on the mind of the scientific discoverer. It was seen that reason has insight only into that which it produces after a plan of its own, and that it must itself lead the way with principles of judgment and force nature to answer its questions." But in his general philosophic formulation of this insight, Kant overlooked the fact that the "principles of judgment" with which thought approaches objects are purely hypothetical in character and are approved or rejected according as they work out in experimental construction of objects. Accordingly, his philosophy, though called critical, was at bottom a revival of dogmatic rationalism, since he held that knowledge requires a fixed stock of *a priori* concepts that are imposed once for all upon objects. The inherent difficulties in this position conspired with the constantly increasing emphasis upon experi-

mental verification to discredit the older empiricism and rationalism alike, and led to the formulation of the doctrine that all general ideas, or concepts, are originally purely hypothetical, gaining certainty as they work successfully to interpret and organize observations and to direct further fruitful experiments. In placing the standard of value for concepts in their use, instead of their structure, the resulting functional empiricism becomes truly critical, assigning a distinctive important rôle to concepts, a rôle not capable of being played by facts and observations by themselves, but insisting also upon the need of experimental test.

**HYPICSICLES.** — See GEOMETRY.

**HYSTERIA.** — Among medical men there is the greatest difference of opinion regarding this topic; some deny the existence of a special disease under this name and would group the patients under other headings, while others include all cases that cannot clearly be diagnosed in other ways. In other words, for some hysteria does not exist as a medical entity, for others it is the name for a scrap basket into which cases are thrown if they do not fit into the regular pigeonholes. It is, therefore, difficult, perhaps impossible, to define the term in any manner that will be satisfactory to all, but it may be said that the best opinion is that hysteria is a disease of a nervous character, with varied manifestations which may simulate the conditions in many organic diseases, nervous and otherwise.

The symptoms in hysteria have been the subject of much discussion, and on the limitation of the symptoms depends the conception of the disease. The symptoms in this disease are extremely varied, and in a general way may be confused with corresponding symptoms in other diseases. The following classes of symptoms may be distinguished: (1) emotional instability; (2) abnormal suggestibility, which Babinski regards as the chief characteristic of hysteria, to the extent of holding that the other accompanying phenomena of the disease are due to the suggestion of the examining physician or the patient's reading; (3) sensationalism due to an exaggerated ego, which leads to a desire to win notoriety and sympathy in any way whatever; (4) motor disturbances, *e.g.*, convulsions and tremors as well as paralysis and motor defects; (5) sensation disturbances; (6) vasomotor, trophic, and secretory disturbances, about which, however, there is little agreement. Jelliffe, in the best account of the whole hysteria problem, has given the broadest expression to hysteria in defining it as "a general tendency to certain reactive expressions," which have already been noted above. Babinski throws aside the classical symptoms

As noted by Charcot and his followers as artifacts and poor observation, and attributes the disease wholly to suggestion. Other psychological explanations of hysteria have been advanced, and in general it may be said that the psychological hypotheses are more satisfactory than those of a physiological nature, *e.g.* those in which attempts have been made to correlate the symptoms with cerebral conditions. The most important of the psychological explanations are those of Janet and of Freud. The definition of Janet, which gives his general explanation, is as follows: "Hysteria is a form of mental depression, characterized by the retraction of the field of personal consciousness and by the tendency to the dissociation and the emancipation of systems of ideas and of functions, which by their synthesis constitute the personality." The symptoms are due to a narrowing of the field of consciousness, to an inattention which produces in general an amnesia. The anesthetics are, according to this view, due to lack of attention to the sensations from the body and the paralyses to a similar cause. The sensation elements are grouped in a subconsciousness, if we may speak of such a thing, and they are there combined just as are the conscious perceptions. The combinations give rise to impulses which are not consciously controlled, and there appears to be a splitting or a doubling of the personality.

Most authors agree, that although the hysterical manifestations do not become obtrusive until the third and fourth decades of life, the impressions that lead to the manifestations are obtained during the first fifteen years. The explanations of Babinski and of Freud indicate the possibility of hysteria formation in children. The abnormal stimulation of bright children, the fixation of the attention upon his health, and the permitting a child to daydream help in the formation of the characters that become hysterical. The vicious habit of obvious concealment from maturing children of all matters of a sexual nature, with the consequence of the acquisition of false notions, and the harsh treatment of childish fears lead to the formation of abnormal modes of reaction and to repressions and concealments of emotional states which may become nuclei for hysterical manifestations in later life. **IBN EZRA, ABRAHAM BEN MEIR (ABEN EZRA)** (1092?–1167) — A Jewish scholar, poet, philosopher, and mathematician. The first period of his life was spent in Spain up to 1140,

his home being in Toledo; the rest of his days was spent abroad, mainly in Italy. Ibn Ezra traveled much, and, in addition to the countries of the Mediterranean coast, visited France and England. His reputation rested for several generations on his commentaries on the Holy Scriptures, for he raised the art of Biblical exegesis to the degree of a science. He helped to revive Hebrew scholarship outside Spain. Ibn Ezra also wrote on grammatical terms in Hebrew, on style, and meter (*Zahot*, 1145). In his philosophical works, traces of Neoplatonic influences may be found. His mathematical writings were numerous and include works on the peculiarities of the numbers one to nine (*Sefer ha Ehad*), on arithmetic (*Sefer ha Mispar*), on the calendar (*Sefer ha Ibbur*), on the astrolabe (*Keli ha Nehoshet*) on three chronological questions (*Shalosh She'elot*); and composed astronomical tables (*Luhot*), and translations of the astrologer Mashallah. He is the subject of Robert Browning's poem, *Rabbi Ben Ezra*.

**ICELAND** — A large mountainous volcanic island in the North Atlantic Ocean (latitude) 63° 24'–66° 32', (longitude) 13° 32'–24° 35' W. Area, 40,437 square miles, climate comparatively mild, especially in the south. The population is 83,000 (1909), engaged chiefly in sheep raising and in fishing.

**History and Government** — The effort has been made, but on very slight evidence, to identify Iceland with the Thule of Pytheas, traces of Irish settlers (monks) were found by the first Norse discoverers. The Norwegians began to migrate to Iceland in the year 874, and in the next sixty years the island was fully settled. Government, in the form of an aristocratic republic, was organized in the year 930. Christianity was introduced in the year 1000. The Icelandic republic lasted until 1264, when Hakon, King of Norway, helped by the long-continued feuds between noble families of the island, was able to induce the Icelanders to be incorporated in the Norwegian monarchy. Iceland with Norway was united to Denmark in 1397. The main events under Danish rule to the opening of the nineteenth century are as follows: Introduction of the Reformation, practically complete in 1550 when the Danes had become the real national leaders, the last Catholic bishop, Jon Arason, and his sons beheaded, the grant of a monopoly in Icelandic

trade to a kind of colonial company of Copenhagen merchants, 1602 — an economic blunder of the Danish government, which brought the island to the brink of ruin, abolition of the Althing in 1800, which meant the sweeping away of the last traces of Icelandic independence.

In the nineteenth century, especially after 1830, there was a marked revival of national feeling and a struggle for national independence, resulting in 1843 in the restitution of the Althing in the form of modern legislatures (advisory only). The constitution of the millennial year, 1874, gave the Althing legislative power subject to the veto of the King, the executive power being in the hands of a governor. The present constitution, adopted in 1903, gave the Althing increased power and placed the executive power in the hands of a minister, an Icelandic residing in Iceland and having a seat in the King's cabinet.

**Language and Literature** — The main body of the settlers of Iceland having come from Norway, the language naturally was developed from the West-Northern dialects of that country and got its literary form in Iceland on account of having been comparatively early put to literary use; it has been preserved far better in Iceland than in any of the other Scandinavian countries. The modern written language differs from that of the Sagas about as much as Tennyson's language differs from Shakespeare's. This has the far-reaching educational result that every boy and girl has access to real classics, at the same time interesting to youthful minds. It is impossible to understand the intellectual characteristics of the people without reference to the national literature which is taught in all schools.

**The Icelandic Literature** comprises 1 Eddas — *Sæmundar Edda* (Older Edda), a collection of cosmogonic, epic, and didactic poems, collected without doubt in Iceland and largely composed there. *Snorra Edda*, a textbook of mythology explaining the constantly recurring metaphors (*Kennangar*) of the "Scalds," giving the myths of the Scandinavian race and copious quotations from the older poets, showing their use in poetic technique.

2 Sagas, which can be divided into three groups: (1) Historical sagas, mainly by known authors, as Snorri Sturluson's *Heimskringla* (history of the kings of Norway); the *Sturlunga saga*, written by a contemporary and participant in the events, Sturla Thordason. (2) Family sagas relating the actions of the leading aristocrats at home and abroad, founded always on fact, but idealized for æsthetic motives. The form in some instances is concise, as in the modern short story (Maupassant); such is the story of Gunnlang, the Worm Tongue. Sometimes it is of epic proportions; stories of whole country-sides or families, as in *Njala*, the most artistic and famous of all. (3) Romantic and legendary sagas often written under foreign influence (*Chansons de geste*, Briton lays, etc.). These

are almost entirely medieval, and lack the realistic spirit of the genuine sagas. The Eddas and sagas belong, it may be said, to the period c. 850-1300.

Besides the Eddic poetry, generally simple in form, — as *Beowulf*, — is the scaldic poetry, court poetry in praise of kings and princes, extremely artificial in form. To the period 1300-1500 belong the historical ballads (*rimur*) and some splendid religious poems in the old scaldic meter, as Eysteinn Asgrimsson's *Lula*. From the fifteenth down to the nineteenth century, there was a lull in the intellectual life of Iceland, broken, however, by a few notable productions, as Hallgrímur Pjetursson's *Passion Psalms*, the sermons of Bishop Jon Vidalin, and the poems of Stefan Olafsson and Benedict Grondal (the elder).

The poetic renaissance came in the nineteenth century, coinciding very nearly with the political awakening. The leader in this development was Jonas Hallgrímson, whose influence was felt to the end of the century. The chief poets of the later romantic school, 1850-1880, were Steingrímur-Thorsteinson, Benedict Grondal the younger, and Matthías Jochumson. To this period succeeded that of realism (1882), inaugurated by the poet-journalist Jón Olafsson. Lyric poetry reached its height in this period in Hannes Hafstein, author of the spirited ballad, "The Death of Skarphedinn." The realistic impulse naturally gave rise to novelists, of whom the greatest is Gestur Pálsson, and to dramatic art. The latter is stimulated by the establishment of a permanent theater at Reykjavík.

**Educational Beginnings** — Iceland having been settled mainly by the Norwegian aristocracy, the intellectual standard was naturally very high from the beginning. The vikings and local chiefs who emigrated to Iceland were often men who had traveled far and wide, and had seen the civilization of the Celt, the Frank, the Saracen, and Byzantine. On the other side, Christianity in Iceland was introduced more as a political than a religious measure, and its sponsors were the weightiest men of the land, the æsthetic and moral ideas are still closely connected with the old belief. The people are almost without exception Lutherans, the State supporting the Lutheran Church, but there is complete religious liberty. The island forms one bishopric with 105 parishes. In earlier times the educational supervision was entirely in the hands of the clergy. Primary education was always well provided for, the children being taught at home by their parents or by peripatetic teachers. The pastor would visit each family in his parish once a year, examining the children in the elementary branches, if it was found that a child had not received proper training, the pastor had the power to order it taken away from the parents and educated at their expense by some more competent person.

**Present Conditions** — Since the new public school system was introduced, 1907, great progress has been made. Illiteracy is practically

## ICELAND

unknown, and almost everybody can write and knows the elements of arithmetic. Young and old are very fond of reading, and the young people acquire on their own accord further information, especially a knowledge of Danish, of later years also of English, and thus gain access to larger literary fields, the ancient and modern Icelandic literature, as well as newspapers and periodicals, are eagerly read. Each town has a public school, and there are a number of higher schools: a classical college at Reykjavik with about 100 students (a continuation of the old cathedral schools at Hólar and Skálholt), two *real* (or scientific) schools, three schools for women, and some public high schools. At Reykjavik are the following special institutions: a normal school, a school of navigation, a commercial college, and a technical school, also agricultural schools at Hólar and Hvannaeyri.

The three professional schools, of theology (est. 1847), medicine (est. 1876), and law (est. 1907), were in 1911 incorporated into the University (*Háskóli*) of Iceland, which also embraces a faculty of philosophy and history, literature, and language of Iceland. The university was inaugurated Oct. 4, 1911.

The national library (*Landsbókasafn*) at Reykjavik has the most complete collection in the world of books printed in Iceland (73,000 volumes and 6400 Icelandic Mss.). Besides the college library at Reykjavik, with a large and valuable collection of books and Mss., Iceland has three county libraries. The national archives (*Ríkiskjalasafn*, est. 1882) have the safe custody of all civil and ecclesiastical records more than thirty years old. The archaeological museum (*Forngrafsafn*), established 1863, has about 6000 objects. The society of naturalists (*Íslenska náttúrufræðislag*), established 1889, has a museum of natural history. All these collections are housed in the national library building.

Of learned societies, etc., must be mentioned the Icelandic Literary Society (*Íslenska náttúrufræðisfelag*), established 1816, the Icelandic Historical Society (*Íslenska sögufélag*), established 1902, the Agricultural Society, etc.

The financial estimates of 1910-1911 carried a total of 2,930,000 crowns (\$785,240). Of this amount 502,000 crowns (\$134,436) were voted for the Church and education, and 145,000 crowns for scientific and literary purposes. Thus it appears that 22 per cent of the total budget was for intellectual and religious institutions.

Iceland has about a dozen printing establishments (the first introduced in 1530), which at present issue about twenty newspapers, published once or twice a week, and some ten periodicals. During the last century many Icelanders emigrated to America and established flourishing settlements in North Dakota and Manitoba; they publish journals of their own, which are also much read in Iceland.

### ICKELSAMER, VALENTIN (1500?-1541?).

— The author of the first German grammar. He was born in the old free city of Rothenburg on the Tauber and studied first at the University of Erfurt and then at Wittenberg, where he was attracted by the fame of Luther and of Melancthon. In 1525 he held the position of a German schoolmaster in Rothenburg, which city was then agitated by the socialistic movement later culminating in the peasants' rebellion. Ickelsamer took an active part in this movement, in consequence of which he had to flee from the city. He went to Erfurt and from there to Augsburg. There, in 1534, he published his *Deutsche Grammatica* (*German Grammar*) in which he made a strong plea for the study of the mother tongue. The book contained interesting remarks on orthography and etymology, but its chief object was to show a new method of teaching reading based on the phonetic value of the letters. In this Ickelsamer was about three hundred years ahead of his time, for it was not until the second half of the nineteenth century that the old alphabetic method was finally discarded in the schools.

F. M.

**IDAHO, STATE OF** — First organized as a territory by Congress in 1863, Idaho was admitted to the Union in 1890 as the forty-fourth state. It is located in the Western Division, and has a land area of 84,290 square miles. In size it is a little larger than Kansas, nearly twice the size of Pennsylvania, and would make ten states the size of Massachusetts. For administrative purposes it is divided into twenty-three counties, and these, in turn, are divided into school districts of irregular and varying size. In 1910 Idaho had a population of 325,594, and a density of population of 3.8 people to the square mile.

**Educational History** — Owing to the small number of inhabitants in the territory, little was done toward the establishment of schools previous to 1870. In that year the census returns showed only 466 pupils in the schools of the territory, and a total school population of only 888. By 1875 the school population

had increased to 3852; by 1885, to 15,399; by 1890, at the time of the admission of the state, it had increased to 27,311; and by 1908 it had reached 85,216. In 1875 the laws which had previously been passed were gathered up, added to, and reenacted in the form of a new school law for the territory. The territorial controller was made *ex officio* territorial superintendent of public instruction, the auditor of each county was made *ex officio* county superintendent of schools; and three trustees were to be elected to take charge of the schools of each school district. The main lines of the present school system were laid down in this law; the chief changes since that time being in the increase of the powers and duties of the county and state school officials, at the expense of the district organizations. The trustees of each district, under the law of 1875, examined and licensed all teachers, adopted textbooks, and generally managed the schools, while the superintendents collected information, made reports, and apportioned funds. A county school tax of from two to five mills was levied for the support of the schools. In 1874 there were seventy-seven school districts, fifty-three schoolhouses, three school libraries, and 2030 pupils in the territory. The increase of the territory in both population and schools was slow during the eighties, was more rapid after its admission as a state in 1890, and has been still greater since 1900. For some time the progress of the schools was retarded in certain counties by trouble with the Mormons, but after 1890 this seems to have disappeared. In the revised school law of 1883 the office of county superintendent was created and separated from that of county auditor, teachers' institutes were begun, and the functions of the State Superintendent's office were enlarged. In 1887 the separate office of State Superintendent of Public Instruction was created. Since the admission of the state, educational progress has been rapid.

The act of admission gave the state a large amount of land for educational purposes. The common schools received the sixteenth and thirty-sixth sections in each township, or a total of 3,068,231 acres; two townships, or 46,080 acres, were given for a state university, 40,000 acres were given for a state school of science, which, in 1907, was added to the state university endowment fund, 100,000 acres were given for normal schools, 40,000 acres for a state academy, and 40,000 acres for a state industrial school. The constitution fixed the minimum sale price at \$10 an acre, but the sales so far made have been for more than twice this price. Only about one tenth of the school lands are now under lease. These lands will, in time, sell for a good price, and the funds thus created will yield a large income for education. The state constitution of 1890 made very detailed provision for a state system of education. A State Board of Education and a

State Board of Land Commissioners were created; the public school fund and lands were carefully safeguarded, a minimum price of \$10 an acre was set on all school lands; any form of aid to sectarian or religious schools or societies for any purpose, as well as religious tests and the teaching of religious tenets, were forbidden, compulsory education was authorized, the university was located, and the title to university lands was confirmed; and the territorial office of county superintendent was abolished, the probate judges of the county being made *ex officio* county superintendents. In 1892 the University of Idaho was created, and the same year the first state teachers' association was organized. In 1893 a free textbook bill and a compulsory education law were enacted, and state normal schools were established at Lewiston and Albion. In 1896 the constitution was amended to provide for the re-creation of the office of county superintendent. In 1899 the State Textbook Commission was reconstituted, and its work made more definite. In 1901 the Idaho State Academy, a secondary and technical school, was established at Pocatello, and a State Library Commission and traveling libraries provided for. In 1903 the Idaho Industrial Training School, a reform school for boys and girls, was established at St. Anthony. In 1905 the State Board of Education was given power to issue teachers' certificates of a higher grade, valid anywhere in the state; and the compulsory education law, long a dead letter, was revised and strengthened, and county probation officers provided for. In 1907 three six-weeks normal schools were organized. In 1909 rural high schools were established, a State Board of Examiners was created, the system of certification was changed into a full state certifying system, required meetings of school trustees were provided for, and a state school law commission was created. In 1911 this commission reported, and its report was accepted by the legislature, and a new school code enacted. This materially enlarged the powers of the State Board of Education, changed the plans for certifying teachers and apportioning school funds, and made changes in the management and instruction in all rural high schools.

**Present School System.** — At the head of the school system is a Superintendent of Public Instruction, elected for two-year terms by the people, and an *ex officio* State Board of Education, consisting of the State Superintendent of Public Instruction, the Secretary of State, and the Attorney-General. There are also a State Board of Land Commissioners, created by the constitution, and composed of the members of the State Board of Education, with the Governor added, a State Library Commission, consisting of the State Board of Education, with the President of the State University added; a State Textbook Commission, consisting of the State Superintendent of Public

Instruction and six others, appointed by the State Board of Education, two to be practical business men and four to be teachers of at least five years' experience, and a State Board of Examiners, who read and grade all examination papers and grant all teachers' certificates for the entire state. To the State Board of Education is given general supervision over the schools of the state and the preparation of a uniform course of study for the elementary and high schools of the state. The State Superintendent acts as the executive officer of the Board; apportions the income of the school fund semi-annually; visits the counties, and holds meetings with the county superintendents; makes rules and regulations for the conduct of teachers' institutes, and appoints assistant conductors for each one, prepares and distributes all blanks and forms used, and makes a biennial report to the Governor. He or she (women have held the office continuously since 1899) is also a member *ex officio* of the Boards of Trustees of the two State Normal Schools, of the State Academy, and of the State Industrial School.

The State Board of Land Commissioners is charged with the duty of locating, protecting, renting, and selling the school, university, and other lands granted to the state by the General Government by the act of admission. The State Library Board has charge of the traveling libraries of the state, and is directed to cooperate with public and other libraries anywhere in the state. The State Textbook Commission selects the textbooks to be purchased and supplied to the schools of the state, high schools included, and makes six-year contracts with the publishers.

In each county there is a County Superintendent of Schools, elected by popular election for a two-year term. He (or she) must be a practical teacher of at least two years' experience in Idaho, and must hold at least a first grade teachers' certificate to qualify for the office. He is required to hold monthly meetings with his teachers, to visit each school each term, to apportion the school money to the districts, to conduct an annual teachers' institute, may require trustees to make repairs, or to abate a nuisance, may transfer pupils and their quota of funds from district to district; keeps all records, and makes an annual report to the State Superintendent of Public Instruction.

In each school district a board of three school trustees are elected, one each year, at an annual school election. District lines may be altered and new districts created by the Board of County Commissioners. Any district may establish a kindergarten or a high school, and all must provide a five months' term of school and have an average daily attendance of five. Trustees have charge of all school property, and are empowered to employ teachers and fix their compensation; by vote of the district may build, rent, furnish, or sell schoolhouses and

sites, may spend 25 per cent of the school money for fuel, janitor, supplies, and equipment; must spend 3 per cent of the school money for the school library, may dismiss pupils; must compile an annual school census of all pupils six to twenty-one in the district, and must publish an annual financial report. Teachers must make a yearly report to the County Superintendent of Schools. Any district having a valuation of \$150,000 may be organized as an independent district by the County Commissioners. Such independent districts have six trustees, who have, in addition to the powers and duties of trustees of ordinary districts, power to levy a special tax sufficient to provide a nine months' school. If a district employs 35 teachers, it may also employ a superintendent and adopt its own textbooks.

**School Support** — No state tax is levied, but a required county tax of not less than five nor more than ten mills is levied, and any school district may vote a local district tax up to twenty mills. The apportionment of income from the state school fund is made to the counties on the sole basis of the number of school census children. In the counties all county taxation, fines, and license money, are added, and the total is then apportioned to the districts, one third equally to each, without reference to its size, and two thirds on the basis of school census, less 5 per cent, which is withheld for apportionment to the rural high schools. District trustees must levy a tax sufficient to provide five months of school, and the voters of any district may vote a further tax up to a total of 20 mills. Independent districts have special taxing privileges.

**Educational Conditions** — Of the population of 1900, 15.2 per cent were foreign born, 57.7 per cent were males, 3.5 per cent of the total population were Indians, and 1.7 per cent were Chinamen. But 6.2 per cent lived in cities of 4000 or over, while the remainder lived in country districts or in little towns. The state is sparsely populated, large areas being practically uninhabited. The chief occupations are mining and agriculture. The compulsory education law has long remained unenforced. It was revised in 1905 and made more definite, and a probation officer was appointed for each county to assist the Judge of the Probate Court in dealing with the worst offenders. By the new law children eight to sixteen years of age are required to go to school the entire time the schools are in session, though children over fourteen are excused if they have completed the eighth grade, as are all children who are instructed at home or who are physically or mentally incapacitated, or whose labor is necessary for the support of themselves or their parents. Trustees are required to report all delinquent children to the County Superintendents of Schools, who in turn reports them to the Probate Judge.

In material conditions the schools have made

very rapid progress within the past fifteen years. Many of the town and high school buildings are substantially built and fairly well equipped. The average value of the school buildings of the state is about \$3000. The schools are rapidly being graded and standardized. All schools follow a state course of study. All pupils who complete the eighth grade pass the uniform state examination, and this certificate is required for admission to the high schools of the state. Manual training, domestic science, and agriculture are included in the state course of study as optional studies, and a number of schools are reported as making a beginning in these subjects. Two towns are reported as offering regular instruction in manual training. In a few places large consolidated schools have been established, and the pupils are transported to the central school. The state has a good school library system which has been in existence for a long time. Each school district must make yearly additions to its school library; the traveling library system is efficient, and any town or city may levy a tax of one mill for library support. On petition of twenty voters in any school district, an election must be called to vote on the question of a similar library tax on the property of the district.

**Teachers and Training** — For the training of new teachers the state maintains two state normal schools, and since 1907 has maintained three summer schools, offering a six weeks' course of instruction. The certification standards are better than in many other states, and the certification plan has an especial merit in that it provides for a partially graded series of examinations leading up to the highest diploma.

**Secondary and Higher Education** — The state maintains the Academy of Idaho at Pocatello, and the University of Idaho at Moscow (*qv*). The Academy of Idaho offers preparatory, business, and technical courses. The University of Idaho is the only institution of higher learning in the state. High schools are developing rapidly, considering the sparsity of population, there being fifty-one public and private high schools on the University of Idaho list of inspected institutions in 1908, and new schools are being organized each year. The union-district high school law of 1909, and the authorization of two-year agricultural high schools in the same year, will add a new stimulus to their development. The state maintains the Idaho Industrial School at St. Anthony, a reformatory institution for both sexes, and in 1909 established a state institution for the deaf, dumb, and blind of the state, who had heretofore been cared for elsewhere, under the supervision of the State Board of Education. E. P. C.

**IDAHO, UNIVERSITY OF, MOSCOW, IDA** — A coeducational state institution established in 1889. Its government is in the hands of a board of nine regents appointed by the Governor. In addition to the college courses, preparatory, music, engineering, and agriculture courses are offered. The entrance requirements are sixteen units. Courses are offered in the college of letters and sciences leading to the degrees of A B, B S, Mus B, and B S in domestic economy, as well as the A M and M S. The college of agriculture gives a four-year course leading to the degree of B S, and a short winter course of a general nature. The college of engineering provides four courses in different departments of engineering, each leading to the appropriate degree. The State Teachers' Certificate is given to those graduates with the A B or B S degree who have taken courses in education. The enrollment in 1910-1911 in all departments was 527. The faculty consists of fifty-four members, of whom nineteen are full professors.

**IDEA AND IDEATION** — Ideation denotes either the act of thinking or the course, the stream, of ideas, according as ideas are regarded as manifestations of a soul substance or spiritual entity, or as mental contents which in their associations and sequences make up the mind. Upon a third view, it expresses the function exercised by ideas, the results they effect in subsequent experience. So far accordingly as the word is not a synonym for the process of thinking (*qv*), its meaning depends upon that assigned to the term "idea."

Historically, the term "idea" dates from the Platonic philosophy. With him, it means an absolute, unchanging, immaterial archetype, standard, or pattern, which the manifold changing particulars of sense that are called by the same name partially share in and represent. It was the form, the nature, the essential character of a set of particular existences. It was their universal, generic, and also their end, their completion, or perfect reality. Through its presence, and only through its presence, are changes controlled, or made other than an aimless, chaotic flux which as a flux is unknowable because not enduring long enough to have any assignable character. Within the world of physical change or becoming, these ultimate immaterial essences appear as mathematical forms. Mathematical relations supply nature with all its regularity and recurrence, with whatever is constant, or resembles constancy, amid the scene of change. They also supply the only conditions through which nature may be, in any genuine sense, known, be matter of science. The usual charge against the Platonic theory of ideas is that it confused mental concepts with things. If the charge means that Plato began with psychical existences or even with logical abstractions and ended with hypostatizing them, it quite misses

the method and object of Plato. He began with changing objects, acts, and beliefs, and concluded that self-consistent beliefs, stable modes of behavior (individual and social), permanently real objects (and no object not permanently real can be truly real at all) all imply unified eternal essences, which as unified and eternal must be immaterial. This meaning of the term (or of its Latin transliteration of the Aristotelian *eidos*, species, namely) lasted through the entire scholastic period, nominalism alone denying the objective existence of archetypal standards of action and belief. Moreover, through the use of final causes in the medieval science of nature, these standard patterns, in the form of the ends for the sake of which events occur, were assumed also to be the keys to the natural sphere. Even to-day, any one who believes in absolute eternal objective standards or types of justice, truth, law (whether natural or moral), etc., to which particular sets and events tend to conform (or should conform) accepts the essentials of the Platonic doctrine of ideas.

Quite early in modern thought, however, the term "idea" began to change its signification, taking on a more distinctively mental coloring. The notion of objective pattern shaded over into that of internal design, a mental copy according to which an action is carried on, the notion of objective end similarly shades into that of *conscious* intent, purpose as a mental copy of some result to be accomplished. In this way, the term "idea" came to designate any object so far as that object was held in mind, whether for purposes of action or thought. According to the scholastic theory of knowledge, the *species*, the kind, was always the real object of knowledge, even in dealing with a particular thing; that is, in *this* table the table-character is what is grasped by intelligence, whatever does not take the form of such a universal is incognizable. John Locke also called the immediate object of the mind in knowledge an idea, but according to him general characters are never directly apprehended objects or simple ideas. On the contrary, sensible qualities, red, hard, loud, sweet, etc., are the forms, the ideas, which mind grasps or "knows" directly. But Locke also accepted the notion that many of these qualities exist only in *mind*, and so he tended (though with some ambiguities) to hold that the objects of the mind in knowledge are mental objects only. Locke's influence practically determined, accordingly, the subsequent sense of the term "idea" — namely, mental event, occurrence, existence, especially if any cognitive force is attached to the mental existence. However, even this restriction was not always observed, idea was often used to designate any mode of so-called psychic existence, such as a feeling, desire, etc. (The word "thought" has also been used in the same loose style.) On the other hand, some surviving flavor of the earlier intellectual connota-

tion clung to the term, so that, following Hume, many psychologists reserved the term for secondary or revived mental events, keeping the terms "sensation," "feeling," "impression" for the primary.

The significance of the term is still further confused by the fact that it has developed a sense intermediate between the original Platonic objective one and the modern psychic one: a logical usage to denote meaning (*what is meant*), conception (*what is conceived*), the object of intellectual reference as distinct from the act of referring. The fundamental importance of meanings in mathematics, the fruitful way in which these meanings interact for the production of new meanings which no inspection of the original meanings could have revealed, the objective coherence of the resulting systems, have led to the formation of a school of Neo-realism which insists that the science of mathematics proves the independent existence of intellectual essences, not subject to the flux of time and non-physical in character. Moreover, many critics have pointed out that the psychic school confused ideas as meanings with ideas as private, psychic existences, thus making knowledge impossible, since knowledge requires that sensation, image, idea, have a stable reference beyond its own existence. The use of hypothetical meanings as tools of inquiry has meantime suggested still another sense for the term "idea" — that of tentative hypothesis, suggestion, theory. This interpretation mediates between the two conceptions of meaning as pure objective essence and idea as mere psychic existence. As uncertain and tentatively used, the hypothesis or suggestion is mental, in its application and possible outcome, if confirmed, it is subjective.

**IDEALISM** — In the history of thought, idealism covers two things very different from one another, each kind including many varieties and both distinct from the meaning of the term "idealism" as employed in life. In the latter sense, idealism means a praiseworthy *moral* attitude, consisting in devotion to high aims, to ideals, even at the expense of personal loss in material comfort and financial gain. In its technical philosophical meaning, the two types of idealism are characteristic of ancient and modern thought, respectively. The former is primarily a teleological theory of the cosmos, of nature, the latter is primarily an assimilation of nature to consciousness. Classic idealism was a systematized method of interpreting nature from the standpoint of final cause (see CAUSE). It held that nature exists for the sake of realizing purpose, the ultimate

purpose being the Good. The degree of reality possessed by any temporal or phenomenal form of existence is accordingly measured on the scale of the degree in which it embodies or realizes the End, the Good. Reason, intelligence, was conceived as either the highest, the final, good of existence or at least as an indispensable element in the culminating end. It was not conceived, however, as either the efficient cause of nature or as the stuff out of which apparently physical things are made. Nor was the proof of idealism sought in psychological or epistemological grounds. On the contrary, the theory of knowledge was such as would now be termed realistic. It held that the human knower, the individual mind, became intelligent or rational through the process of knowing objects that exist independently of it, by means of appropriating to itself the amount and kind of ultimate reality embodied in them. In the phraseology of Aristotle, sensation is a realization of the sensible qualities of objects; imagination of their form so far as still immersed in particular cases; reason of their universal form, free from particular limitations. And while Plato and Aristotle, the two great names of classic idealism, disagreed in many respects, they were at one in holding that our mental operations are to be viewed and explained from the standpoint of objective reality, not objective reality from the standpoint of our operations of knowing. Consequently, while much is made of reason as explaining the order, the harmony, and proportion found in nature, little is made of the chief concept of modern idealism, consciousness, so that the term hardly appears as a significant conception.

Modern idealism may be said to have found its points of departure in two convictions. (a) The most certain, the best known, thing is an individual's own inner life, his play of emotions, hopes, fears, pleasures, pains, ideas, memories, etc., what was later termed consciousness, or the psychic. (b) all objects as known are relative to the processes of sense-perception and judgment that are involved in knowing them. (1) From the feeling that the surest, the most accessible region, in fact the only directly accessible and absolutely sure thing, is the individual's own inner life, it was but a step to the conclusion that the sole escape from skepticism as to the possibility of scientific knowledge of the world, as well as the sole way of explaining how a physical world can interact with a mental world, is to resolve that external world itself into psychic material. The assimilation of the objective to the subjective has been the characteristic trait of every form of modern idealism. (2) The conviction that sense qualities are relative to the individual percipient had been held by some of the sophists in antiquity. Under the prevailing conditions of science at that time, however, such a theory could issue only in intellectual nihilism, the denial of all stable knowledge.

The case was quite otherwise with the beginnings of modern science. All those interested in removing from science the incubus of explanation through final causes fastened upon it by scholasticism and in substituting a mechanical mode of explanation, were interested in reducing physical nature to a homogeneous medium, to mass, motion, space, and time capable of interchangeable statement in terms of one another. The most obvious obstacle to the accomplishment of this ideal was the diversity of static qualities presented by natural objects. By the simple device of relegating color, sound, smells, tastes, to the mind of the percipient, this obstacle was overcome, and the residual "real" object was left with only properties that lent themselves to mathematical formulation and mechanical explanation. Hence, it was those most interested in the progress of physical science that were most emphatic in declaring the purely mental nature of the "secondary" qualities. Galileo, Descartes, Hobbes, all taught that they are "effects" produced by the real object on the sentient mind, useful as signs to point to powers in the object, but having a purely mental status.

It was the work of Berkeley (*qv*) to carry this line of argument into a thoroughgoing idealism. With acumen and vigor he pointed out that to common sense, to the plain man, the real object and the perceived object are identical, that as a matter of fact the so-called primary qualities (extension, resistance, and the spatial-mathematical properties generally) are inseparably bound up with the visible and tangible qualities, and hence that the so-called material real object was but an "abstract" idea. Hence the entire world of known and knowable objects was mental *esse* equals *percipi*. Berkeley, as a theologian, had no difficulty in attributing the permanent and orderly relations manifested in the world of perceived objects—their "laws"—to the work of divine mind, leading us to expect, in regular and reliable ways, one perception to follow upon another. Hume (*qv*), with his antitheological bias, had no difficulty in showing that upon Berkeley's own principles, God, being unperceivable, has no valid status, and that mind itself must be resolved into the simple flux or stream of changing perceptions.

Since his time, idealism has flowed in two separate channels. Empirical, psychological, or subjective idealism has stood for the Berkeleyan resolution of existence into perceptions and their associations, simultaneous and successive—minus, of course, his assumption of spiritual soul substance, divine and human. But since one school of philosophic theory, and upon the whole, the orthodox one, had always attributed slight, or even negative, importance to perceptions as compared with conceptions, in determining the framework of knowledge and in giving certainty, there arose another

## IDEALISM

type of idealism which identified "Reality" with conceptual, or rational, contents; whose motto was *esse equals intelligi*. This school of rational idealism is also termed objective realism, because it has taught that thought relations constitute objects independently of relation to any individual percipient, which, as merely individual, is only sentient and hence incapable of general (scientific) knowledge except as it is informed by the same *a priori* or objective reason that constitutes the objective world itself. Its chief motif has been the necessity of permanent and universal relations for the existence of objects of scientific and systematized knowledge, and the identification of these relations with the various functions of rational thought. This type of idealism was introduced by Kant and was carried to its culmination by Hegel, who, however, introduced another and independent conception, that the objective manifestation of mind is found more adequately presented in social life, in the state, and in the historic phenomena of politics, art, and religion than in nature. Schopenhauer, in turn, gave idealism a further distinctive turn by finding the clew to the nature of existence in will rather than in rational thought.

It may almost be said that, barring materialistic and agnostic philosophies, these two types of idealism divided the field between them for a century after Kant. At present, there are many signs that the idealistic movement has, temporarily at least, spent its force. At least, there is a strong realistic tendency in active progress. This movement is too recent and too close to permit of any accurate and just assignment of causes. Some of the main reasons for it are, however, obvious. One is the exhaustion of interests in the type of problems that gave idealism its original impetus. Another is a number of inherent inconsistencies that no type of idealism has completely overcome. Allied to this, is the seeming deadlock between the two kinds of idealism. Moreover, there is a growing feeling that the complete resolution of everything into psychical existence, whether sentient or rational or a fusion of them both (as in Bradley and Royce) in breaking down all distinction between mind and anything else, defeats its own end—that of attributing some distinctive, significant place and efficacy to intelligence in the scheme of existence. Concretely, the most influential force has probably been the development of the doctrine of biological evolution and its evidence that mind, instead of being the sole monopolistic existence, is itself an expression of life, and the means by which life secures its most effective control of the environment in the furtherance of its own active processes. At present, the realistic movement has both a pragmatic and an intellectualistic form, the two agreeing in their common opposition to traditional idealistic systems rather than in a positive body of convictions. **IDEALISM AND REALISM IN EDUCATION** — Two idealistic systems of philosophy have had a peculiarly intimate connection with the theory of education, the Socratic-Platonic movement in antiquity and that of German transcendentalism in recent times. They have also exercised a significant influence upon educational practice. The effect upon practice has not been so much direct as reflex, consisting chiefly in affording a supposed intellectual justification for procedures that originated independently of philosophy. The Platonic idealism, so far as it affected education, was a development of the method pursued by Socrates in his endeavor to arrive at fundamental principles and standards of action. Socrates urged that since no man would voluntarily do violence to his own being or deliberately seek his own harm, ignorance of his own real nature and its proper end, or good, was the source of all evil doing. Moreover, ignorance was the cause of the divisions, the struggles and factions, of civil life. Wherever there is knowledge or true understanding, dispute is impossible, agreement and knowledge are equivalent. The search for knowledge, the process of learning, is, therefore, of necessity a search for that which all men have in common, and which, accordingly, they have a mutual interest in reaching. Argumentative dispute, the desire to conquer in argument, is *ipso facto* evidence of lack of love of wisdom or knowledge. Its opposite, comparison of ideas with a view to discovering their common basis and intent, Socrates called dialectic. Since opinions and beliefs could differ only if they meant to refer to the same thing, a common underlying reality was implied in them.

In the dialectic method there were accordingly three elements: (a) The presupposition

of an objective universal as the proper subject matter of knowledge, (b) the implication of this universal in all particular opinions and beliefs, (c) the possibility of its discovery by systematic comparison of particulars. The resultant discovery formed the concept or definition of the object in question — justice or whatever ethical reality might be the object of search. Unless there were such objective universals, the moral anarchy of subjectivism was inevitable; anything was good or right that seemed to be right or good to an individual at any particular moment. The further consequence was social discord and strife, for only an objective universal gave anything common, that is supplied a basis of unity.

Plato extended the Socratic method from moral realities and knowledge of them to all realities and the proper method of knowing them. Knowledge as distinct from private shifting opinions is possible only by virtue of unchangeable substantial universals in which all the particulars of a class participate and through reference to which they can be defined and understood. These objective universals were the Platonic Ideas (*q v*) or Forms. Moreover, since all particulars were changing, they were capable of order and uniformity only in the degree in which their changes tended toward their universal. It was then their end, their good, or perfection. Hence true or dialectical knowledge consists in knowing the ends for which natural things exist, a thing without an end is a mere monstrosity.

There are many phases of the Platonic idealism that are reflected in his own educational theory. In fact, education was of central importance in his philosophy, since it was only by a proper method of education that men could become skilled in the use of the dialectic method and be enabled to turn the eye of the soul from the sense appetites and opinions, that correspond to mutable particulars, upon the eternal universal. But a more important consideration for our present purpose is the fact that while the details of the Platonic scheme remained practically without influence, the two chief aspects of his method became firmly embedded in all higher education. These were the setting of dialectical above physical inquiry, and of discussion of final causes above search for efficient causes. Physical science dealt with just the particular and changing things which, according to this philosophy, were relatively unreal, they corresponded only to sense knowledge and mere probability, or opinion. More important was the elaborating and comparing of ideas and beliefs, matters of classification and definition, rather than of observation and experiment. Knowledge of antecedent conditions and constituent (physical) elements was, moreover, held in contempt compared with knowledge of the end or purpose for which things existed. And this latter was a matter of development

of meanings rather than of external observation of facts.

That for over fifteen hundred years education followed these lines is too well known to need recording. There is also no need to say that causes quite independent of the Platonic idealism were responsible for the neglect of the physical sciences and mechanical methods of analysis. But the Platonic dialectic as elaborated through the Aristotelian logic furnished the intellectual tools for the entire patristic and scholastic system of education, and the philosophic ideas through which the leading ideas were defended and systematized. Even in the humanistic educational ideal, the feeling that preoccupation with ideas and beliefs is intrinsically more worthy than inquiry into natural existences is to a considerable extent a survival of the dialectic side of classic idealism.

In the general sense of the term, accordingly, Realism in education began with the reaction of the Renaissance period against the supremacy of those forms of subject matter that could be dealt with by pure logic. It contended that such subject matter consisted simply of abstractions at its best, and at worst simply of words. Moreover, since only ideas and beliefs that were already in the mind, or that were already current, could be analyzed, defined, and systematized by purely dialectic method, this method confined men to tradition and authority. In the interest, then, of both reality and mental emancipation, the Realism of the sixteenth and seventeenth centuries called men from ideas to things. Francis Bacon is the great representative of this movement, philosophically, so far as philosophic Realism influenced education it was chiefly through his work. The older methods were, however, too deeply entrenched to undergo much more than slight transformations in externals. The Baconian Realism was but prophetic; there were no well-developed methods of inquiring into fact and no organized subject matter available for educational purposes.

The transcendental idealism of the later eighteenth and early nineteenth century had a symbolic and an institutional form, the former represented in education by Froebel, the latter by Hegel. Both are dominated by the idea of a progressive development or unfolding of a spiritual self-consciousness (which is the principle of totality) in and through the particulars of nature and human experience.

According to romantic (or symbolic) idealism, particulars (especially those approximating mathematical form) are suggestive, illustrative, allegorically symbolic of the absolute truth. Accordingly they may be employed to awaken in the mind of infancy the absolute truth or reality already implicit or latent in it. Froebel's great natural aptitude for perceiving the educative force of plays and games, and modes of occupation was accordingly utilized

by him in the interest of a religious, quasi-mystic, quasi-mathematical formalism, the formalism being explained and sanctioned by its supposed correspondence in the realm of feeling and sense with spiritual essence and law in the absolute sphere

Hegel's idealism was substantially an outgrowth of his opposition to the subjective idealism he attributed to Kant and Fichte. According to him, absolute mind is externalized in physical nature, but truly objectified in social institutions and history. The state is objective reason and will. Only by participating in this realized spirit can the potential mind, latent in individuals, get rational substance or body for what otherwise is a mere empty capacity for consciousness. The unqualified necessity of social institutions as the agencies through which the latent rationality of individuals is to be awakened and developed or brought to full reality, was thus the final lesson of the Hegelian idealism. The accomplishing of this end constitutes education.

Remarkably enough, the great metaphysical realist, Herbart, reached essentially the same conclusion by an opposed route. According to him, there is no one final, all embracing, absolute reality, there is a plurality of reals. Moreover, there is no intrinsic tendency in the individual mind to evolve according to its own inner law into realization of supreme reason or spirit. There is only the capacity to react in a characteristic way to every contact with a real. Education is thus not the growth or development of the mind in accord with its own inner nature, it is a forming or shaping of mind through the presentation of the external reals which operate upon it. The earlier reactions persist as ideas and form the mental material through which all later presentative reactions are received and organized. By controlling the earlier presentations, in terms of which the later are "appereceived" and made effective, we can accordingly control the formation of mind and character, this latter being, indeed, but the complex of patterns formed by past contents as they operate in determining the reception and organization of new contents. In deciding, however, the order and sequence of the presentation of materials, Herbart was almost wholly under the influence of the notion of recapitulation of the culture of the past. As the earlier contents in the history of the individual dominate the assimilation of the later, so these earlier contents are to be assimilated to the culture products of the earlier stages of civilized mankind. Thus, in spite of their radically diverging bases, the Hegelian and the Herbartian systems, as applied to education, agree in the primacy of social material, the former emphasizing the value of institutions, the latter of culture products.

It is out of the question in a matter involving as many important considerations and issues as the idealistic-realistic controversy to do

more than point out some of the chief points involved in passing judgment upon it. From the earlier historic division it appears that the question concerns the respective places of meanings and of natural existences in the scheme of experience. From the latter discussion, the issue is seen to have to do with the respective functions of inner development and outer control. If one commenced the investigation of the problem with educational interests uppermost, one's most probable conclusion would be that existence and meaning, internal growth and outer direction, are mutually complementary, not exclusive rivals. As matter of fact, the beliefs of the greatest number of men have always been dualistic rather than exclusively idealistic or realistic. But, again, from the standpoint of that direction of growth of character and intelligence that we call education, what is needed is not a division of the field into separate regions, or into two disconnected kinds of force, but a cooperation of two distinctions which are both relative to the evolution of life and experience. In short, from the standpoint of education, the need is for a philosophy which translates the static divisions of mind and world, inner and outer, that characterize traditional dualisms into dynamic interacting factors of growth, thereby going beyond both traditional idealism and realism. J D

See DUALISM, HUMANISM AND NATURALISM

### IDENTITY — See SELF

**IDEOMOTOR (Idea and Motor)** — Many active processes are dependent upon ideational processes rather than upon sensory stimulation. These motor processes are said to be aroused through the action of ideas and the processes thus aroused are said to be ideomotor in character. Thus the activity of an insane person may be aroused through the presence of certain fixed ideas (*qv*). The significance of the word in psychological discussion is that it draws attention to the fact that many motor processes depend upon central nervous activities and are not dependent upon external sensory stimulations.

C H J

**IDIOCY** — The term specifically used to denote the lowest grades of mental defect, although it has been, and unfortunately is still, sometimes used loosely to apply to almost any grade of deficiency. In the definition adopted by the British Royal Commission on the Feeble-minded and agreeing with common usage, an idiot is described as "a person so deeply defective in mind from birth, or from early age, that he is unable to guard himself against common physical dangers," being differentiated on this somewhat economic basis from (1) the Imbecile (*qv*) in that the latter, while "capable of protecting himself

under usual circumstances, is incapable of earning his living," and from the Feeble-minded (*q.v.*), who, while "capable of earning a living under favorable circumstances," is incapable of "competing on equal terms with his normal fellows."

**Classification and Incidence** — For purposes of description idiots are frequently divided into three groups, high, medium, and low grades, although obviously there is no definite line of demarcation between these groups any more than there is between the larger division of idiot, imbecile, and feeble-minded. Sufficient evidence exists for the statement that there is a continuous distribution of cases through all grades of deficiency from the merely dull or stupid person to the lowest grade of idiot.

The following typical classification is employed by the New Jersey Training School for Feeble-minded, "The low-grade idiot is the perfectly helpless child, the middle-grade idiot the one who is able to feed himself, but who eats almost anything, the high-grade idiot, the child who eats with some discrimination, discarding that which is not food." More commonly idiots are divided roughly into two groups, the profound, or complete, and the superficial, or incomplete, and again on the basis of their disposition into apathetic and excitable (Ireland). In the first case "the defect is so profound as to involve the fundamental organic instincts, and even that of sucking is absent" (Tredgold).

Perhaps the most satisfactory classification for general purposes is on the basis of the clinical varieties and characteristics and their etiology. Such a description will apply to all degrees of deficiency. Thus Tredgold, following for the most part the clinical groups proposed by Ireland, first divides deficient into two classes, primary and secondary, according as the deficiency is due in the first instance to hereditary factors, "the results of inherent defects of the germinal plasma" and including probably about 90 per cent of the cases. In the secondary class, including about 10 per cent of the cases, "there is no marked heredity, and no inherent ability to develop, but the growth of some portion or the whole of the brain is interfered with, or arrested, by disease or other adverse environment." These terms, primary and secondary, as thus defined, are proposed as being more accurate than the more usual terms, "congenital" and "acquired."

To these classes a mixed class of cases must, as Shuttleworth and Potts point out, be recognized "in which the actual lesion supervenes upon a brain originally imperfect in development, and to such cases, occurring at a crisis of early life, has been given the name *developmental*."

The chief clinical varieties recognized are (Tredgold): (1) simple amentia corresponding to the "genetous" group of Ireland and presenting "no special distinguishing features

other than the anatomical and physiological anomalies to aments in general," and divided according to etiology into porencephalic, sclerotic, and hydrocephalic; (2) microcephalic; (3) mongolian, (4) epileptic (*q.v.*); (5) vascular, toxic, or inflammatory, again subdivided into the three classes given under (1); (6) syphilitic; (7) infantile cerebral degeneration; (8) cretinism (*q.v.*), (9) amentia due to nutritional defect; (10) amentia due to isolation or sense deprivation.

The number of persons classified as idiots depends somewhat on care and method of classification. According to Tredgold there were in England in 1906 "approximately 8654 persons corresponding to 0.25 per thousand of the entire population. The class is thus about one third as numerous as the imbeciles and comprise about 6 per cent of all amounts." As regards sex, there is a small preponderance of male idiots.

Reference should be made to the idiot savants or idiot geniuses. They furnish evidence for the specialization of mental defect. They may be gifted, for example, with unusual memory of one sort or another, — numbers in the case of some of the arithmetical prodigies, in music, art, or craftsmanship, but signally wanting in most, if not all, other respects (F. Peterson, *Idiot Savants*, in *Popular Science Monthly*, Vol. L, p. 237). For the details of methods of training that have been attempted, beginning with the early attempts of Itard (*De l'Education d'un Homme Sauvage*, 1801) and the notable work of Seguin (*Idiocy and its Treatment by the Physiological Method*, 1866, republished by Teachers College, Columbia University). The reader is referred to these writings and the appropriate chapters in the following selected bibliography.

**ILLINOIS COLLEGE, JACKSONVILLE, ILL** -- A coeducational institution founded in 1829 and chartered in 1835. Interested and influential in its foundation was the "Yale Band," consisting of seven men from Yale College, as well as the Presbyterians of the surrounding country. The institution became coeducational in 1903, when the Jacksonville Female Academy and the Illinois Conservatory of Music were merged with it. The requirements for admission are fifteen units. The college grants the degrees of A B and A M. The faculty consists of twenty-one members.

**ILLINOIS, STATE OF** -- Originally a part of the old North-West Territory. Organized as a separate territory in 1809, and admitted as the twenty-first state in 1818. It is located in the North Central Division, and has a land area of 56,000 square miles. In size, it is a little larger than New York and New Jersey combined, a little smaller than New England, and about the size of England and Wales. For administrative purposes, the state is divided into 102 counties, these in turn into townships, and these into school districts. In 1910 Illinois had a population of 5,638,591, and a density of population of 100.6 persons per square mile. About two fifths of the population of the state is in Chicago and the adjoining residential towns.

**Educational History** -- The first school of which there is any record was kept in Monroe County, near St. Louis, in 1783, and other schools were opened in neighboring counties before many years. The first schools in Cook County were opened in 1816. (See CHICAGO, CITY OF.) The first constitution in 1818 made no mention of education. The first legislation with reference to schools was in 1819, when the Legislature incorporated three academies, at Edwardsville, Carlyle, and Bellville. The charters of the Edwardsville and Carlyle academies provided for the free instruction of poor children, and, as soon as financial conditions would permit, girls were to be admitted. In 1825 the first general school law was enacted. This provided for common schools in every county, free to all white children, three to twenty-one, for the subdivision of the counties into school districts of not less than fifteen families, and for the election of three trustees for each district by the voters at a called school meeting. The trustees were to examine and hire teachers, to hold and lease property for the schools, and to make an annual statistical and financial report. The support of the schools established was to be derived from local taxation, from the income of the sixteenth section lands and funds, from an apportionment of 2 per cent of all state taxes collected, and from five sixths of the income of the state school fund. Each district was empowered to provide school buildings and equipment, and the clerk of each county commissioner's court was directed to

collect and transmit to the Secretary of State the annual school returns. No state, outside of New England, had so advanced a law, the people of Illinois were not educated up to such an advanced conception of education, the law was nullified two years later, and the state lost its chance of educational leadership in the new West. In 1827 the whole or half support of a school by taxation was made optional with the voters of each district, and no man could be taxed for schools without first obtaining his consent in writing. For the next twenty-five years little was accomplished, and church schools furnished the chief means of education for the state. Excepting for a law providing for the election of three Township Trustees and a County School Commissioner to look after the school lands, and the creation of a county school fund in 1835 by depriving teachers of one half of the public money due to them for the year and with it establishing a permanent school fund, nothing whatever with reference to education was done for ten years. In 1837 provision was made for the incorporation of townships, and for five Township Trustees instead of the three School Land Trustees, in case of incorporation. This board of five Trustees was to manage all the schools, and to report regularly to the County Commissioner of their county. Teachers were to be certificated by the Township Trustees before they could receive any public money. In 1841 the school laws were revised, and the 1827 law with regard to taxation was finally repealed. In all townships not organized under the 1837 law the previous provision, requiring three Township Trustees and a County School Land Commissioner, was reinstated, and in addition three School Directors were to be elected for each school district, under either form of township organization. These new officials were to manage the school of their district, to care for the building, to employ the teacher, and to visit the school. This cumbersome method of combined district and township administration has persisted until the present time. In 1840 and in 1843 there was legislation with reference to academies, as these were then being established in numbers. A few were chartered with the specific privilege of receiving state money on the same basis as the public schools, but this plan was never generally adopted. In 1845 instruction in the schools was required to be wholly in the English language, and the people were required to determine annually, in school meeting, whether they would tax themselves to support a school. The limit of local taxation was placed at 15 cents on the \$100 (1½ per cent). In 1848 a new state constitution was adopted, but this made no mention of education, further than to provide for the exemption of school property from taxation and to permit the Legislature to invest school districts with the power to assess and collect taxes. It was not until the constitution of 1870 that a sepa-

rate article on education was inserted. Unlike Indiana, the constitution of Illinois did not pave the way for new features in school administration, but on the contrary merely recorded what had been established previously by legislation and fully accepted by the people.

The first attempt to secure a form of supervision for the schools was made in 1845 by the designation of the Secretary of State as *ex officio* State Superintendent of Common Schools, and the County School Commissioners as *ex officio* County Superintendents of Schools. These *ex officio* County Superintendents were directed to visit and inspect schools, to examine and license teachers, and to make an annual report to the Secretary of State. The Secretary of State, in turn, was to recommend maps, charts, apparatus, and textbooks, to endeavor to reduce to a uniform system the means of supporting schools throughout the state, and to report biennially to the Governor. In 1854 this *ex officio* system was abandoned, and the separate office of State Superintendent of Public Instruction was created to be filled in 1855, and biennially thereafter, by popular election. Until an election could be held, the Governor was to appoint, and the first appointee was to report a bill to the next Legislature which should provide for a free tax-supported system of public education for all the children of the state. The proposed law was accepted by the Legislature of 1856, and marks the beginning of a real state system of schools. Up to this time private and denominational schools had occupied the field; from now on public schools developed rapidly and soon gained the ascendancy. The new law defined and enlarged the duties of the State Superintendent; retained the County School Commissioners and changed them into County School Superintendents; retained the previously established township and district school boards; permitted the establishment of district school libraries; provided for a two mill state school tax, to be added to a 6 per cent income from the school funds, and for local taxation; required a six months' term, authorized bonds for school buildings; and abolished the "rate" and made the schools free. This law is the foundation of the present system, no fundamental changes having been made since that time. During the next twenty years, the terms of the State and County Superintendents were changed to four years each; the terms of Township Trustees and District School Directors were so changed as to secure a retiring one third each year; township high schools were authorized; and special laws for city districts were framed. In 1872, 1889, and 1909, the school law was revised, but no fundamental changes were made.

In 1839 a state institution for the education of the deaf and dumb was established at Jacksonville. In 1859 an institution for the education of the blind, and in 1865 an institution

for the training of the feeble-minded were also established at the same place. In 1871 a state reform school was established at Pontiac. In 1853 the state teachers' association was formed, and in 1864 a County Superintendents' association was organized.

The new constitution of 1870 was the first to contain a mandate for the establishment and maintenance of a system of public schools. It also safeguarded all permanent school funds, prohibited aid to sectarian or denominational schools, prohibited teachers and school officers from being interested in contracts; and provided for a County Superintendent for each county. The office of State Superintendent is not mentioned in the constitution. Women were first permitted to vote at school elections in 1873. In 1874 a law was passed prohibiting the exclusion of children from any school because of race or color, this law being still in force. In 1857 the first state normal school was established at Normal, and a board of trustees, termed the State Board of Education, was created to manage the school. In 1869 a second school was established at Carbondale, and opened in 1874. In 1867 the Illinois Industrial University (now the University of Illinois) was established at Urbana. In 1869 county normal schools were authorized, and two county normal schools were at once established, one for Cook County (Chicago) and the other for Peoria County (Peoria). Two additional state normal schools were established in 1895, and a fifth such school in 1889. A child labor law was enacted in 1891, and revised in 1903. Kindergarten classes were authorized in 1895, classes for deaf children in 1897, and classes for crippled children in 1903.

An educational commission was created by the Legislature of 1907 and in 1909 reported a recodification and condensation of the existing school laws; a plan for the establishment of a State Board of Education with sufficient power to enable it to be of real educational service; a plan for County Boards of Education for each county to supervise the schools of the county; a new and graded plan for the certification of teachers, which, had it been adopted, would have given Illinois the best certifying law in the Union; a plan for making the township the unit of organization for schools, and a simplification of the present system of school organization by abolishing the District Boards of Directors; recommendations for the improvement of teachers' institutes, and a minimum salary law providing for minimum salaries of \$315 and \$385 per year for teachers holding the two grades of teachers' certificates. Only the first measure, the recodification and condensation of the existing laws, could be got through the Legislature, and the chance of finally organizing a strong and efficient state school system was lost. This Commission made a second report in 1911, but no fundamental changes were made in consequence.

**Present School System.** — As at present organized, the school system of Illinois is as follows: A State Superintendent of Public Instruction, elected by the people for four-year terms, heads the system. There is no State Board of Education, or analogous body, the so-called State Board of Education being merely a Board of Trustees for the State Normal School at Normal. The State Superintendent is required to supervise the public schools of the state, to interpret the school law, decide appeals, and advise school officers as to their duties; to advise County Superintendents as to the construction of school buildings; to grant state certificates to teachers, valid in any county, and to revoke them for cause; to visit the charitable institutions of the state; to prescribe the forms of reports; and to make a biennial report to the Governor. He may also authorize County Superintendents to procure institute instructors, remit forfeitures of the school fund for any failure on the part of districts; require school officers of all kinds to report; and may also request private institutions to make reports. But little power and few functions are assigned to the State Department, and the office is clerical rather than creative.

For each county there is a County Superintendent of Schools elected by the people for a four-year term. There are no County Boards of Education. The County Superintendent is required to look after and sell any township school lands remaining; to visit every school in his county at least once each year, to advise and assist school officers, to conduct a teachers' institute each year, examinations for teachers' certificates each quarter, and examinations for normal school and university scholarships as necessary, to examine the Township Treasurer's bond, and to make an annual examination of his books, to collect fines from the civil authorities and to deposit them to the credit of the school fund, to apportion the state and county school funds to the townships and parts of townships, and to notify the district trustees of the amount distributed, to see that an annual school census is taken by each district, and to make quarterly and annual reports of his acts and visits to the county authorities and annual reports to the State Superintendent. He is also empowered to require reports from all school officers, and to remove district officers for cause, to direct Township Treasurers in the keeping of their books, to renew teachers' certificates without examination, and to revoke them for cause, and to determine disputes among school officials.

Smaller than the county are the Congressional townships, each of which is a school township as well as a civil township. Fractional townships with less than 200 children may be consolidated with adjoining townships. For each township, three Township Trustees are elected, one each year, at the annual April

school elections, to hold office for three years each. These Township Trustees must hold semiannual meetings, must apportion the school fund *pro rata* on census to all districts, and must elect a Township Treasurer, for two-year terms, who acts *ex officio* as clerk of the township board. They may also divide the township into districts, and, on petition of the voters, change the districts or consolidate them. The Township Trustees report annually in detail to the County Superintendent, or, in case the township is cut by a county line, to the County Superintendents of both counties. The Township Treasurer has charge of all moneys; keeps all school accounts for the township and the districts, loans the principal of the township funds, makes an annual financial report to the County Superintendent, receives the taxes collected and pays all orders of the school districts, and acts as an overseer of the financial and business affairs of the district school authorities.

For each school district, within the township, the voters must elect a Board of School Directors of three members, for three-year terms, one being elected each year. The Board is required to manage the schools of the district; to determine the studies, apparatus, and textbooks of the schools, and to loan textbooks to indigents; to employ teachers, and to dismiss them for cause, to levy taxes for the support of at least a six months' school in the district, free and equally open to all, to notify the Township Treasurer of the amount levied, to appropriate funds for specific purposes, to borrow money, and to issue bonds, to make an annual report to the Township Treasurer and to the electors of the district at the annual election, and, in case the district lies partly in two townships, to report to both Treasurers. It is with these District Boards of Directors that the chief control of the schools of Illinois rests. Districts having 1000 or more inhabitants, and up to 100,000 are managed by Boards of Education, which have all of the powers granted to District Boards of Directors, and, in addition, the power to maintain schools up to ten months, to examine teachers by examinations supplemental to the county or state examinations, to buy, lease, and condemn school sites, to employ a Superintendent and a secretary, and to print an annual report and course of study. Cities of over 100,000 inhabitants, of which there is only one, are governed by a board of education of twenty-one, appointed by the mayor, and have still larger powers. (See CHICAGO, CITY OF.) Women are eligible to election to any school office, and, if properly registered, may vote at any school election.

The system of school administration in Illinois is still further complicated by the presence of high school boards. Any township, any two or more townships or districts, and any district having 2000 or more inhabitants, may form a high school district, by petition

and election. For such high school districts a high school board of five trustees must be elected. The high school district is separate and distinct from the common school district, but may levy taxes and conduct a high school in the same manner as such a district.

**School Support** — Illinois originally received 985,066 acres of land from the sixteenth section grant, made by Congress for the support of all schools. This has all been sold excepting 6375 acres. The fund produced by the sale of this land belongs to the township in which the land was located. To this has recently been added the county fund, created by the act of 1835, which amounted in 1906 to \$161,703. The combined fund now amounts to about nineteen millions, and is loaned out by the township treasurers for the benefit of the schools of their townships. The state also received 3 per cent of the sale price of government land within the state, for education, five sixths of which went to form the permanent state school fund and one sixth to the college fund. To the five sixths constituting the permanent state school fund was added \$335,592.32 from the surplus revenue of 1837, being a little more than two thirds of that received. Both funds were borrowed by the state and spent. They amount, nominally, to nearly one million dollars, upon which the state pays interest at the rate of 6 per cent. This, with a state two mill tax, constitutes the state's contribution, and in 1908 amounted to \$896,276.58, or to about 3 per cent of the cost of maintenance of the school system. The interest on the township fund, and the proceeds of fines, forfeitures, and fees, each produced about 3 per cent more. District taxation is the main support of the schools, and produced 88 per cent of the cost of maintenance in 1909. The remainder came from miscellaneous sources. Boards of directors and boards of education in all the school districts of the state, regardless of size, are permitted to levy a local tax of  $1\frac{1}{2}$  per cent on their assessed valuation for maintenance, and  $1\frac{1}{2}$  per cent for building purposes. Bonds for further sums may be voted by the people. All school money is apportioned to the counties, from the counties to the townships, and from the townships to the districts on the sole basis of the number of children under twenty-one years of age in each subdivision. The income from the township permanent fund is apportioned to the districts on the same basis.

**Educational Conditions** — The state is a rich agricultural and manufacturing state, with many railroads and much business. Notwithstanding its large city population, nearly one half of the total population yet live in country districts. Of the total population, about one fifth are foreign born, and about two per cent are negroes. In illiteracy the state had but 4.2 per cent. The educational system of the state is characterized by an excessive

development of local management and control, and little centralization in either management or support. Cook County, containing the large and wealthy city of Chicago, with its large expenditure for education and its many excellent schools, and the small, relatively inefficient, and poorly financed rural schools of the black belt of southern Illinois, stand at opposite extremes of the educational system of the state, as well as of the state itself. The 10,613 ungraded schools, with that number of teachers, are supervised by something like 40,000 school officials, not including the county superintendents.

Many districts report themselves as unable to provide a six months school within the limit of taxation allowed by law. One third of the districts were reported as without a library, and 924 of the 13,058 schoolhouses in the state are reported by the county superintendents as unsanitary and unfit. Six hundred and eighteen schools enrolled less than eleven children. The district system has been so strongly entrenched that no laws for the consolidation of schools and the transportation of pupils have so far been enacted, though strongly advocated. Sixty-six schools in the state report kindergartens, 134 as having manual training, 70 as having domestic science, 102 as having special teachers of drawing, 185 as having special teachers of music, and five cities provide day schools for the oral instruction of the deaf. These extra educational advantages are confined almost entirely to the larger cities. The private and parochial schools of the state enrolled 16.6 per cent of the public school enrollment, and in Chicago 35 per cent.

**Teachers and Training.** — Of the teachers employed 53 per cent were college graduates, 7 per cent were normal school graduates; 21.5 per cent had attended some normal school, 14 per cent had not had the equivalent of a high school education; and 10.5 per cent were beginners. Examinations for teachers' certificates are held quarterly in the counties, and two grades of certificates are granted, valid for one and two years respectively and in the county where issued. The standards for these are low. Special certificates may be granted in almost any subject. State certificates, valid in any county, may be issued on examination by the State Superintendent. Cities may superimpose additional examinations for city certificates. As a means of improving teachers in service, an annual county institute of at least five days must be held by each county superintendent, which is free only to the holders of teachers' certificates. For the training of new teachers, the state now maintains five normal schools, all of which in 1910 maintained summer sessions for teachers in service. The city of Chicago also maintains a city normal college, requiring high school graduation for entrance. Entrance to the state normal schools is from the grammar schools,

and the course is four years in length. For high school graduates, a two years' course is arranged, and a one year's course is also arranged for those who must teach after one year. In 1907 the legislature authorized the four then existing normal schools to arrange for a degree course of two years of graduate study, leading to the degree of Bachelor of Education. College graduates may obtain the degree in one year, and three eighths of the work may be done *in absentia*.

**Secondary Education.** — Any school district having a population of 2000 may establish its own high school and elect a high school board of education to manage the school. City boards of education in cities of 1000 or over, may establish high schools as a part of the graded school system of the cities. Any township may by petition and election establish a township high school, and two or more

In addition to professional departments maintained by the larger of the above institutions, there are also five independent theological schools, four independent law schools, and five independent medical schools, nearly all being located in Chicago.

**Special Institutions** — The state maintains the following special institutions for the education of defectives: the Illinois School for the Blind, at Jacksonville, the Illinois School for the Deaf, at Jacksonville, the School of the Soldiers' Orphans Home, at Normal, the State Training School (Reformatory) for Girls, at Geneva; the Illinois State Reformatory for Boys, at Pontiac. townships, or districts, may unite to form a union high school. On the petition of fifty voters in any high school district, the question of whether or not a manual training department shall be established by the trustees must be submitted for a vote, and if a majority votes in favor of it the trustees must establish such a department. These laws have resulted in the formation of a large number of high schools, there being about 700 in the state at the present time.

**Higher and Technical Education** — The University of Illinois (*q v.*) founded in 1867 as the Illinois Industrial University, and located at Urbana, stands at the head of the public school system of the state. It is one of the largest of our state universities, and offers a wide range of instruction. The state also contains a large number of private institutions of learning.

#### ILLINOIS, UNIVERSITY OF, URBANA,

**ILL** — An institution founded by the state as a land grant college in pursuance of the act of Congress of 1862. The institution was incorporated in 1867 as the Illinois Industrial University, and opened to students in 1868. At first labor on the farm was made compulsory, but was soon discontinued. In 1870 shop instruction in the mechanics was introduced for the first time in an American university. Women were admitted in the same year. The university received legislative authority to grant degrees and diplomas in 1877, and in 1885 the present title was adopted. In 1896 the Chicago College of Pharmacy became the School of Pharmacy of the University of Illinois, and in 1897 a school of law, known since 1900 as the College of Law, was opened. In 1897 the College of Physicians and Surgeons

of Chicago became the College of Medicine of the University of Illinois. In the same year the State Library School was opened at the university. In 1901 the School, now the College, of Dentistry, was organized. The School of Railway Engineering and Administration was established in 1907. Courses in business administration had already been introduced in 1900. The government of the institution is in the hands of a board of nine trustees elected for six-year terms, and the Governor of the state, the President of the State Board of Agriculture, and the Superintendent of Public Instruction *ex officio*. Students are admitted by certificate from an accredited high school or by examination. The entrance requirements are fifteen units. In addition to the schools mentioned above, a summer session and agricultural experimental station are maintained. The enrollment of students in 1909-1910 was 5118, distributed as follows: graduates, 283, arts, 880, science, 297, engineering, 1303, agriculture, 628, library, 31, music, 61, academy, 334 (discontinued, 1911), summer session, 313, law, 193, medicine, 526, dentistry, 108, pharmacy, 174. The faculty at Urbana includes 140 members of professorial grade and 368 junior instructors and assistants. Edmund James James, Ph D, LL D, is the president.

**ILLINOIS WESLEYAN UNIVERSITY, BLOOMINGTON, ILL.** — A coeducational institution founded in 1850 and comprising four departments, an academy, college of liberal arts, college of law, college of home economics, school of fine arts, and school of music and oratory. The requirements of admission are fifteen units. The four courses, classical, Latin-scientific, scientific, and English, lead to degrees of A B and B S. A high school education is required of candidates who wish to enter the college of law, which confers the degree of Bachelor of Laws at the end of a three years' course. Of the 737 students enrolled in 1910-1911, 241 were taking work in the college of liberal arts. The faculty consists of 42 members.

**ILLITERACY** — A term used to denote the inability to read and write in any language, and applied to those ten years of age or over. In a few foreign countries, and in a very few American states, statistics are also collected which segregate those unable to read the language of the country from the literate, and as an intermediate class. Classified statistics as to illiteracy have been collected by the United States Census decennially since 1840, and similar statistics are compiled and published at intervals by most other nations. The ability merely to read and write represents a very elementary test, and many who are able to pass it are still illiterate in almost every other than the technical sense of the term. Nevertheless, the ability to read and write distinguishes those who may learn and improve their minds from

papers and books from those who are shut off from this source of knowledge. Thus, the percentage of illiteracy to be found in a state or nation is to a very large degree an index of the extent to which the advantages of elementary education have been provided for the people by the government.

Illiterate people should be classified as to age, sex, nationality, and race to exhibit the existing conditions in any intelligent manner. Illiteracy under the age of ten is generally neglected in all educational statistics, so that little can be told, except in cities where a good school census is taken, as to the degree to which compulsory education laws are enforced during the early school period. The next measure of illiteracy, after the total number ten years of age or over, is usually the percentage of the voting population which is illiterate. This is higher than the former, as it includes a larger percentage of older persons. Statistics for those who have passed certain age periods, such as forty or fifty years of age, show a still further increase in the percentage of illiteracy. Classified by sex, the illiteracy of females nearly always exceeds that for the males of the same age, race, or nationality, except that it is less in the United States for the age period of ten to twenty-four years. In some Catholic countries, and in all Mohammedan and Asiatic countries, the illiteracy of the females is markedly higher than among the males. In Turkey, India, and China we find a high illiteracy among the males, and an almost complete illiteracy among the females.

The least illiteracy to-day is to be found among the people in the countries to the north and west of Europe, and of Teutonic or mixed Teutonic stock. It was in these countries that the Protestant revolt made its greatest headway, and the ability to read the word of God and to participate in the church services were regarded as of great importance for salvation. The lowest percentage of illiteracy to-day is found among the Teutonic nations (the German states, Sweden, Norway, Denmark, and Finland), the Mixed Teutonic nations (Switzerland, Scotland, the Netherlands, and England), and in France. As we go to the south and east of Europe, the percentage of illiteracy increases rapidly, reaching its highest points in Spain and Portugal in the one direction, and in Russia, Serbia, and Roumania in the other. Greece, Italy, and the different states of the Austro-Hungarian Empire also have a high percentage of illiteracy.

Various methods are, however, employed to discover the number of illiterates in different countries. In Great Britain it is usual to compile statistics of illiteracy from the number of those who sign the marriage registers by mark; a supplementary test is also afforded by taking tests among the army and navy recruits. On the Continent the statistics of illiteracy are drawn mainly from the conscripts for the army.

## ILLITERACY

In both tests the statistics are of course true only of people at a certain age. In the United States the census accepts a declaration of each person as to his or her literacy. How varying the basis of calculation is shown by the follow-

ing table, in which the term "illiterate" includes all persons unable to write their own language, except in the case of countries marked with an asterisk, where illiteracy is based on inability to read:—

In the United States a very determined campaign has been waged against illiteracy during the past thirty years. The relatively high percentage of illiteracy among the native whites

foreigners into the cities and states of the North Atlantic and North Central groups of states, and particularly the rapid shift in immigration from the north and west of Europe to the south and east, after about 1880; and the increasing state and national consciousness that an illiterate population is a national danger, — all alike have tended to stimulate the American states in their efforts

to abolish illiteracy from among them. Great headway has been made in the Southern states not only in reducing the illiteracy among the colored population, but among the poor native whites as well. The history of education in the different Southern states (see articles on the different Southern State School Systems, ALABAMA, ARKANSAS, FLORIDA, etc.) during the past thirty years is in large part the story of a battle to reduce the illiteracy of their people, to provide elementary educational advantages for all, and to enact and enforce some form of compulsory education and child-labor laws. Arizona and New Mexico have also made commendable progress in reducing the illiteracy of the Mexican portion of their populations. (See articles on the school systems in these states.) In the states of the North Atlantic and the North Central groups of states the efforts to reduce illiteracy have been seriously interfered with by the great immigration of foreign elements, coming largely from countries where illiteracy is high and where primary education is but poorly provided for. The French Canadians from Canada have caused much concern to the mill towns of New England. Similarly the great influx of South Italians, Greeks, and Russian and Polish Jews into the cities, and of Magyars, Slovaks, Lithuanians, Poles, and other nationalities from the south and east of Europe into the mining regions and manufacturing towns of the Northern and Eastern states, have caused much concern there. Schools have been increased in numbers and improved, educational advantages have been multiplied, and in cases extended to the parents also, and compulsory education and child-labor laws have been enacted, revised, and enforced. The results of all of these efforts, in the different parts of the country, has been a marked reduction in the percentage of illiteracy, considered as a total or by states as wholes. But owing to the growth of the country the total number of illiterates has a little more than held its own during the past forty years. (For full detailed figures, by states and for the decennial periods, as well as by race, sex, and ages, see the *Reports of the United States Census*. The Thirteenth Census, for 1910, gives the latest figures available.)

An analysis of the figures contained in these reports gives the following results. In thirty years the percentage of illiterates, ten years of age or over, has been cut in two (17.0 per cent in 1880; 13.3 per cent in 1890, 10.7 per cent in 1900; and 7.7 per cent in 1910). The percentage of illiteracy among the female sex is still slightly greater than for the males, though it has been reduced much more rapidly. Among persons between the ages of ten and twenty-five, however, the percentage of illiteracy among the females is less than among the males. The percentage of illiteracy among the negroes is still high (30.5 per cent in 1910), though this has been more than cut in half during the past

thirty years. The large percentage of illiterates among the colored race in a few of the old slave states raises the average for the race above what it would be for most of the Southern states. Among the white population alone, the percentage of illiteracy has been nearly cut in two also during the past thirty years (9.4 per cent in 1880; 7.7 per cent in 1890, 6.2 per cent in 1900; and 4.9 per cent in 1910). This high average for the country as a whole is the result of adding in the large number of illiterates of foreign birth (native-born whites, 3.0 per cent; foreign-born whites, 12.8 per cent), just as the large number of illiterates among the native-born population is the result of adding in the illiterates of the colored race.

Illiteracy among children has decreased greatly everywhere, and illiteracy is less prevalent in the cities of 25,000 population and over, despite their large foreign-born element, than in the small towns and country districts. The percentage of illiterates among the children of native-born parents is, strange to say, much greater than among the native-born children of foreign-born parents. In the Southern states there are relatively few foreign-born people, and the problem of illiteracy is among the negroes and poor whites. In the Northern and Eastern states there are relatively few negroes, but a large foreign-born population, so that the problem there is among the foreign-born in the cities and the native whites of the rural districts. In the western part of the North Central Division the foreign-born is largely from the north and west of Europe and largely Teutonic in stock, the rural schools are good, and the percentage of illiteracy is the lowest to be found in the United States. Kansas, Nebraska, Iowa, Minnesota, and the two Dakotas are situated in this group, and all have a very low percentage of illiteracy. In the mountain and Western states, if we omit a relatively small number of Indians, the illiteracy is almost entirely among a foreign-born mining and agricultural element in the population.

One significant thing about the tables published, when analyzed closely by states, is the growing illiteracy in the villages and rural sections of a number of the states, particularly the older states. This is partly due to the incoming of a cheaper foreign-born agricultural laborer, and in part to the inefficiency of the rural school and the lack of the enforcement of compulsory education laws by country people. The first is one which is likely to cause the illiteracy of country districts to increase rapidly during the next few decades. As scientific agriculture, carried on on both an extensive and an intensive scale, takes the place of the old style of farming, the size of farms and the number of large farms worked by a scientific agricultural superintendent and cheap foreign labor may both be expected to increase. The problem of education in rural communities will become more and more acute, and the need of a

reorganization of rural education along rational administrative lines will be increasingly felt. (See article on RURAL SCHOOL PROBLEM)

The idea of free schools for all, supported by the taxation of all, is an expression of the fear of an ignorant citizenship. As the problems of government increase in number and complexity, and as the franchise is extended to new peoples and in new directions, the national peril of an ignorant and an untrained citizenship is felt with increasing force. The good of the community and of the State, as much as of the individual, demand as high a general level of intelligence on the part of the masses as is within reasonable attainment, and nowhere is this more forcibly pushed upon the attention of statesmen than in a democracy such as our own. The deeper this conception takes hold of the national consciousness, the more marked will be the tendency not only to stamp out illiteracy in the usual technical sense of the term, but to insist upon the attainment of at least the rudiments of a common-school education before the child is allowed to leave the school and begin work. The recent tendency of our American states to revise their compulsory education laws so as to require attendance at school every day that the schools are in session, the extension of the compulsory education period from fourteen to sixteen, and the Massachusetts insistence upon the ability to undertake the work of the fourth school grade to be considered able to read and write, are all tendencies in this direction. The German and French requirements of the completion of certain grades of work before leaving school are similar illustrations of this tendency.

**ILLUSION** — In many cases the process of perception is so disturbed by the conditions under which it takes place that the resulting image or mental process is not adequate as a representative of the external object from which the percept was derived. Thus if for any reason one sees an object as very small when he should see it as large, an illusion is said to arise. Such an illusion occurs when we look upon human beings from a great height. If we looked at them at the same distance in a horizontal direction, we should see them as larger than when we look down upon them from above. The contrast between two such cases of perception makes it clear that one or the other of these percepts is not adequate to represent the external object. Simple geometrical figures illustrate very clearly what is meant by an illusion. Figure I shows two horizontal lines which are of exactly the same

length. The additional oblique lines, however, so disturb the process of perception that we are

Fig I

unable to recognize the two horizontal lines as equal to each other. In Figure II the long lines are parallel to each other, but the intercepting oblique lines so disturb perception

Fig II

that we see the long lines as converging and diverging, not as parallel.

The reason why these illusions persist in adult life seems to be that there is no motive which would lead us to overcome them. Indeed, the motive is in some cases very strong for the maintenance of certain regular, typical forms of interpretation which are illusory. Thus, it is an illusion when we see a reflected object behind the mirror, but this illusion is due to the general perceptual habit of recognizing all objects as placed in the direction from which light comes, and it would be disastrous to our mental life to overcome this natural perceptual habit. The presence of the illusions is not a large consideration in educational discussions so long as we deal with the practical side of school work. For purposes of scientific study of perception, however, illusions lend themselves as very helpful instances of complexity which are capable of ready analysis and experimental study.

**ILLUSTRATIVE DRAWING** — In the kindergarten and the primary grades drawing is used as a means of expression, paralleling speech, dramatization, song, and play, and preceding written composition. The drawing is kept spontaneous both in selection of fact and invention of form, no direct method being used to improve the form and technique chosen by the child to illustrate, exposit, or narrate his meaning. Later when he begins to write, the making of illustrative pictures accompanies his written compositions. This spontaneous drawing frequently goes under the term "illustrative drawing."

See DRAWING.

## IMAGE

**IMAGE.** — A term used in general to describe the experience which one has when he remembers anything. Primarily the term is applied to visual memory. Thus one has the image of a face which he recognized yesterday. Secondly the term is carried over to refer to auditory and tactual memories and all other recalled experiences. Thus one is said to have an auditory image of the word which he heard an hour ago. Images have different degrees of vividness, completeness, and assertiveness. Thus certain individuals see clear visual reproductions whenever they try to recall their past visual experiences, others have very dim reproductions. An image may lack certain of the elements which the original percept contained. Thus one recalls a building, but is quite unable to supply in his image the details of architectural devices which he originally saw. Finally, one may have an image which haunts him and demands his attention, while on the other hand he may be able easily to set aside the experience as a mere trivial memory. In ordinary usage the term "image" is broadly synonymous with the term "idea." More strictly employed, the image is only one phase of the idea, namely, the content phase, whereas the term "idea" (*q.v.*) refers to the general processes of comparison present in all complex thought.

- GALTON, SIR F. *Inquiries into Human Faculty* (New York, 1883).  
STOUT, G. F. *Manual of Psychology* (New York, 1899.)

**IMAGELESS THOUGHT** — The use of this expression has lately arisen in psychology in protest against the doctrine that thinking and all conscious processes are composed entirely of sensory images, along with present sensations. Thought was regarded as a combination or sequence of pictures, either visible to the "inner eye," or audible to the inner ear, etc., and the practical inference was sometimes drawn that the way to develop thinking power is to cultivate the powers of imagery. When Galton found that good thinkers were often deficient in powers of imagery, at least of visual imagery, doubt was thrown on the image doctrine. It had to be admitted that the image was often a very inadequate picture of the object of thought. The conception of *meaning* (*q.v.*) now arose, an image, however imperfect as a picture, might symbolize or stand for a thing or fact, and serve the purpose of thought as well as a complete and highly colored mental picture. The meaning was the important thing from a practical point of view, but was supposed to be very elusive in consciousness, so that introspection would show only the images with vague halos of meaning and intangible feelings of the tendencies of the image. In consciousness the image was still supposed to be the prominent

## IMAGINATION

feature. But recent experimental studies, in which the effort has been made to describe what is present in mind during actual thinking processes, have found that oftentimes the meaning is clear and prominent in consciousness, while the image, if present at all, is so elusive as to escape detection. Such "imageless thought" is now an admitted fact in some individuals. Whether it is an ultimate fact, as some contend, or whether it is to be explained away as due to a blending of many obscure images, or whether it is composed of sensations of muscular tension and movement (which are sure to accompany any thinking activity), or whether it is a nearly unconscious and automatic process, resulting from previous training in thinking on a given subject, — all these alternatives are still open, as the psychology of thinking stands to-day. From the practical point of view, it would certainly seem that the cultivation of imagery — however valuable this may be on its own account — is not to be regarded as essential to the development of powers of thinking. What is essential is the ability to grasp meanings and relations, and this may best be made the direct object in view — success being tested by ability to handle meanings and relations rather than by ability to handle images.

**IMAGERY.** — See **IMAGE**, **IMAGELESS THOUGHT**, **IMAGINATION**; **MEMORY**, also **EYE-AND EAR-MINDEDNESS**.

**IMAGINARY NUMBERS.** — See **COMPLEX NUMBERS**.

**IMAGINATION.** — This term is employed to indicate that the content of consciousness is made up of images derived from past experiences. In view of the fact that human conscious experience deals very largely with visual content, the word "image" is appropriate in the description of most processes. Imagination is related to memory. In memory the image is an exact reproduction of the earlier experience, or in so far as it departs from the exact reproduction of the earlier experience, it is defective. On the other hand, in imagination memory images are more or less readjusted. Elements of a number of different memories may be brought together in a single new image. Thus, one may construct an imaginary scene in which a number of different actors are brought together. These different actors may each of them be remembered characters, but the whole scene will be an imaginary scene in the sense that these particular persons were never presented simultaneously in experience.

The power which an individual has of thus rearranging his ideas is undoubtedly a very late

product in animal evolution. The higher forms of animal life undoubtedly have memory images, but they do not have the power of working over these memory images into new combinations. The behavior of animals goes to indicate that they never succeed in thinking of new combinations which they may work out in the environment. New combinations in the environment, as appear in the human construction of machinery, indicate a very high development of the power of imagination. For these recombinations of material objects must be anticipated by some recombinations of ideas in the mind. The earlier stages of imagination appear in mythology. Here primitive man, impelled by his desire to explain nature, brought together ideas which are not presented in this combination in his actual experience. Such primitive imagination may be described as mental play. The myths which resulted were of importance not merely in satisfying the momentary demand for an explanation of given phenomena, but they also cultivated the power of mental recombination and furnished the experience out of which grew the principles by which the products of imagination could be criticized, for as soon as primitive man began to consider explanatory systems of ideas he found himself in conflict with others who had made similar efforts to imagine explanations, and each thinker was thus impelled to work out these combinations of ideas which would most validly represent the external conditions. He ultimately became critical of his own imaginations, and abandoned the mythical explanation for a more scientific investigation of the facts. This scientific investigation required, no less than the earlier mythological explanation, a recombination of ideas. But this recombination of ideas was undertaken more critically than the primitive imaginations.

There grew up as a result of this more critical type of intellectual effort what is known as scientific imagination. The scientist has no hesitation in combining ideas in a form which is not immediately suggested by direct observation. Thus in modern physics, light is explained as a system of vibrations and is usually illustrated in classroom work by various gross forms of wave motion which are explained to the student to be representations which he may use in constructing an imaginary picture of what actually goes on when light travels through space. The student is warned during such demonstrations that the pictures which are furnished to him are not exact representations of light vibrations, but merely material which he may use in constructive thinking.

The importance of such constructive thinking for human mental life is unlimited. As soon as man learned to recombine his ideas through imagination, he gained a power over his external environment which he could not have so long as his images were merely reproductions of past experiences. He could now bring together,

first in thought and afterwards in a practical way, elements of his experience which nature would never bring together. He could plan a complete transformation of his surroundings. He could lay out a plan reaching into the future and involving combinations that no individual has ever seen.

Children are sometimes said to be more imaginative than adults. The statement in this unqualified form is not justified by a study of mental development. Mental development progresses in the direction of more and more active recombinations of experiences. Greater activity in this case does not mean that the individual is likely in the later stage of mental life to make more fantastic combinations of experiences. For example, the adult who is acquainted with the laws of zoology cannot imagine a dragon with the same confidence that a child imagines a dragon breathing fire. The adult is limited in his possibilities of imagination because he knows that animal tissue would be injured by contact with fire. In this sense, therefore, his imagination is restricted by his larger experiences. On the other hand, the adult is capable within the limits of his knowledge of physics and chemistry of thinking of more combinations than the child could possibly imagine. He may work out the mechanical principles of physics in a great variety of different kinds of imagery. He has freedom, therefore, to make mental combinations according to certain laws of experience. Indeed, he may for purposes of fiction abandon some of the rigid laws of physics which he knows. He may for example think of various types of flying machines which he knows could not be actually constructed. When such fantastic imaginations are indulged in by adults, they give pleasure and amusement, but they do not attract the same type of belief that they do in young children. The principles of criticism here operate to protect the adult from any serious consideration of his fancies. The term "fancy" is used to mark off these imaginations which are free and amusing, but are not undertaken for serious practical purposes. In the child there is a confusion between fancies and serious imaginings, because the child is not supplied with the canons of criticism which the adult possesses.

Adult imaginations are accordingly more critical, while they are at the same time more numerous and more varied in type. Imaginations may be classified from various points of view. Literary imagination is that type of imagination in which combinations of characteristics and events are worked out for purposes of entertainment or instruction. Scientific imagination is that type of imagination in which the forces of nature are thought of for purposes of explaining phenomena. Mechanical imagination is that type of imagination which is exhibited by the inventor.

The cultivation of the imagination is undoubt-

## IMBECILES

edly an important part of the work of the school. There is danger in school instruction that the child's efforts to make combinations of ideas will be unduly suppressed by the critical teacher. The child whose combinations of ideas are thus suppressed is likely to lose the tendency which he naturally exhibits, because he will regard criticisms as unfavorable to all activity of the imagination. The skillful teacher should lead the child to recognize the value of constructive, critical imagination as distinguished from mere fancy. There should be no abatement of the power to recombine ideas in the forms other than those which are dictated by actual experience, but there should be a gradual increase in the critical power which the child exhibits in the examination and classification of his own imaginations. Where the child shows a disposition to use only one type of mental imagery, he should be encouraged to broaden the scope of his imagination. (See EYE- AND EAR-MINDEDNESS.) The practical interest which the individual attempts to work out constitutes a strong incentive for the cultivation of imagination, for whenever a person is trained to attack intelligently a new situation, he will naturally fall into the way of planning beforehand for this situation. Planning in advance is always a form of imagination.

**IMBECILES, EDUCATION OF** — See DEFECTIVES, SCHOOLS FOR; IDIOCY.

**IMBECILITY.** — A term used to describe a degree of mental deficiency severer than that of the feeble-minded (*q.v.*), but superior to that of the idiot (*q.v.*). According to the definition accepted by the British Royal Commission on the care and control of the feeble-minded, imbeciles are "persons who are capable of earning a living under favorable circumstances, but are incapable from mental defect existing from birth or from an early age (*a*) of competing on equal terms with their normal fellows; or (*b*) of managing themselves and their affairs with ordinary prudence."

From the institutional standpoint the group ranges from the child "who plays a little and tries to help but can do nothing alone, to those who can do simple tasks of short duration, such as washing dishes, scrubbing floors, or sweeping" (Goddard). Because of the frequency of moral weakness and deficiency among imbeciles, they are commonly grouped also according to the degree of moral sense, as moral imbeciles of high, middle, or low grade. See IDIOCY.

Tredgold estimates that the number of imbeciles (in England) corresponds to 0.73 per thousand of the population, being about "half as numerous as the adult feeble-minded,

## IMITATION

and about three times as numerous as idiots." There is a slight preponderance of the male sex.

**IMITATION.** — The term is used in ordinary language to designate any repetition of any act or thought which has been noted by an observer. Thus, one imitates the facial expression of another, or his mode of speech. The term has been brought into prominence in scientific discussions through the work of Gabriel Tarde, who in his *Les Lois de l'Imitation* points out that imitation is a fundamental fact underlying all social development. The customs of society are imitated from generation to generation. The fashions of the day are imitated by large groups of people without any consciousness of the social solidarity which is derived from this common mode of behavior. There is developed through these various forms of imitation a body of experiences which is common to all of the members of a given social group. In complex society the various imitations which tend to set themselves up are frequently found to be in conflict, thus the tendency toward elaborate fashions in dress is constantly limited by the counter-tendency toward simpler fashions. The conflict of tendencies leads to individual variation from the example offered at any given time, and, as a result, there are new examples to be followed. Complex social examples are thus products of conflict.

This general doctrine of Tarde has been elaborated by a number of recent writers. Royce calls attention to the fundamental importance of imitation as a means of social inheritance. The same doctrine is taken up by Baldwin in his *Mental Development in the Child and Race*, and in *Social and Ethical Interpretations*. With these later writers, imitation takes on a significance which is somewhat technical and broader than the significance which it has either with Tarde or in the ordinary use of the term. Baldwin uses the term to cover that case in which an individual repeats an act because he has himself gone through the act. In such a case, one imitates himself, and sets up what Baldwin terms a circular reaction. The principle of imitation is thus introduced into individual psychology as well as into general social psychology, and the relation between the individual's acts and his own imagery is brought under the same general principle as the individual's responses to his social environment. The term "imitation" in this broader sense is closely related to the processes which are described under SYMPATHY (*q.v.*).

The term "social heredity" has very frequently been used in connection with all of the processes here under discussion. Society

tends to perpetuate itself in the new individual in a fashion analogous to that in which the physical characteristics of the earlier generation tend to perpetuate themselves in the physical characteristics of the new generation. Since modes of behavior, such as acts of courtesy, cannot be transmitted through physical structure, they would tend to lapse if they were not maintained through imitation from generation to generation. Thus, imitation gives uniformity to social practices, and consequently is to be treated as a form of supplementary inheritance extending beyond physical inheritance, and making effective the established forms of social practice. C. H. J.

See SYMPATHY; SOCIAL HEREDITY

**Imitation in Education.** — Large reliance upon imitation in education has been defended upon two grounds, one psychological, the other sociological. Psychologically, it is claimed that out-of-school experience shows that the child acquires the larger part of his skill in various directions by imitation, so that economy and efficiency require that it be the chief resource for learning in school. Socially, it is contended that the chief distinguishing feature of social life is identity of mental contents, especially of thought and beliefs, on the part of the various individuals who constitute society, and that this identity is secured by imitation. Largely under the influence of Tarde, older biological theories of society were replaced by "psychological" conceptions of society, and imitation was made the chief, if not the sole, category of social psychology. If this doctrine be accepted, appeal to imitation is not merely a valuable psychological expedient, but is an ethical necessity.

Both of these conceptions are questionable. A common fallacy seems to underlie them both. Wherever there is a social group, people are found doing the same sort of things; and, what is even more important, believing the same sort of things and using the same standards of valuation. Since it is demonstrable that this similarity is acquired, and since it is certain that the younger members of society have learned from the older, it is an easy conclusion that the likeness is due to imitation. But this explanation hardly does more than to take a result and then give it the name of a cause or force. The certain fact that persons do, externally viewed, imitate one another, that is, do alike and think alike, and that this community is essential to society is translated over into a belief that imitation is a natural internal force, working to bring about the likeness. Closer inquiry shows, however, that other causes are chiefly responsible, and that so far as there is a distinctive psychological tendency to imitate, it works effectively only in subordination to these other factors.

Upon the personal side, the initial factor is the tendency of native impulses and acquired

habits to complete or realize themselves in some external form. The child spontaneously, naturally or instinctively as we say, tries to effect something, urged on by the force of his own impulsive tendency. He reaches out his hand, makes babbling noises, tries to throw a ball, to walk, etc. Intent upon his end, he unconsciously selects and adapts anything he notes that might help him. He does what he sees others do in the same situation, not in order to imitate them, — a matter of which he may be quite unconscious, — but as a way of executing his own inchoate tendency. The mere imitation of others, apart from selective use, is found in imbeciles, in the less intelligent children, and in the more mechanical and empty moments of intelligent children. When reliance upon imitation is urged in teaching, the essential thing in the natural situation, personal initiative in a certain direction, is forgotten, and there is substituted for it a servile dependence upon the ends of others. Since the process of selecting and adapting the observed actions of others to one's own results involves intelligence, while taking the acts of others as one's ends abrogates judgment, it is not surprising that objection is made out of school to the latter process.

Further examination shows that imitation, even in its subordinate rôle, is properly called such from without, not from within. Psychologically what occurs is a case of the wider principle of sensori-motor adaptation. While the human infant is not limited to predetermined coordinations of sensory stimulus and motor response, as are the young of lower animals, the necessities of life require that there be some preference for certain forms of behavior in connection with certain modes of excitation. A stimulus of light, for example, at once induces movement of the eyes in fixing and following it. This act operates in turn as stimulus to the body to throw itself into a certain posture, to the arm and hand to reach, and, at times, to follow by tracing the movements of the light. Persons watching a runner, a baseball batter, or one performing a gymnastic feat unintentionally sway the body sympathetically. Externally viewed, there is acceptance of another as a model for copy, psychologically viewed, there is the only completion of the sensori-motor coordination involved in every act of perception. Accordingly, from the side of individual development, "imitation" is but a species of a wider genus. Persons act much alike and think much alike because they are subject to the same stimuli and are urged on by the same needs.

The case works out in a similar way from the social side. Mere imitation would never even make a beginning of a society, because it would only give a number of persons doing the same thing at the same time. A society involves diversity of activities on the part of different persons (division of labor, in

a wide sense of that term) and cooperation of different acts to a common end. But in addition to this co-adaptation of different acts to a single result (which is found in machinery), there must be also an intellectual and emotional appreciation of the common end and of the relation of the diverse individuals to it. This fact has been partially recognized in Baldwin's version of Tarde's theory, for he criticizes Tarde on the ground that his doctrine would apply equally well to a collection of tuning forks where one vibrates in response to another. Consequently he amends the conception to read imitation of *thoughts*, or *mental contents*, not of acts. In effect, this is to surrender the idea of imitation and keep merely the name, for thoughts or mental contents as such, cannot possibly be imitated, being invisible and unobservable. And the details of Baldwin's account show that what he really is dealing with is the various processes by which one person *arrives* at community of beliefs and ideas with others. This confirms our statement that the so-called "imitation" is simply a name for the fact that different persons do, in the same community, think alike, that likeness of thought being necessary to social life, but that it is not a causal factor by which this community of ideas and emotions is brought about.

Educationally, the emphasis upon imitation as the essential fact about society not only fails to throw light upon the causal forces by which social direction is brought about, but in a progressive society sets up a false ethical ideal. It makes identity of belief a good, and the supreme social good, just by itself. Such a standard obtains only in static communities, controlled by conformity to custom, and it is a symptom and a cause of their stationary nature. The intellectual and moral progress of the human race has come through first tolerating and then encouraging divergencies and diversities of thought, — the essence of individuality, — and through the conception that mere identity of thoughts is not an end in itself, but an incident of the accomplishment of other ends. More specifically, it is quite contrary to the spirit of a democratic and progressive society to set up as a conscious end the idea that one, even if he be only an immature child, shall repeat the acts of another so as to arrive at a state of passive acquiescence in the ideas of others. Whether as a psychological method or as a social standard, imitation occupies a subordinate position. J. D.

## IMMIGRATION AND EDUCATION. —

Immigration creates duties for the administration of schools by introducing into the body of citizens elements which are alien in speech, and are generally of lower intellectual attainments than the mass of the community. Broadly speaking, the problem of assimilating the immigrant is the problem of overcoming the contrasts between his condition and that of the older resident, of wiping out the inequalities of social condition introduced by his coming among us. So far as these inequalities result from a different upbringing, the problem of assimilation is that of education in its largest sense. But the educative value of environment, of laws and of institutions, of contact with other and unaccustomed modes of life and thought, are not here in question. It is also impossible here to discuss the difficulties which arise from the places of origin of immigrants. The specific subject to be considered is how far the established agencies of education, the schools, may and do contribute to the assimilation of the immigrant.

It is necessary, therefore, to have not only a very clear view of what the problem is, but also how far the schools are able to affect it. Before going into the details of the situation created by immigration, it may be well to remember the necessary limitations upon the activities of the school administration, and to bear in mind that after the age of fourteen years has been passed the influence of the school system upon any class of individuals depends upon their consent. Our subject, therefore, falls naturally into three divisions, the influence of the schools (a) upon the adult immigrant, (b) upon the child immigrant, and (c) upon the second generation, or children of native birth and foreign parentage. In its first phase, the predominant influence of the school concerns language, in its third phase, general education. In the second phase the two influences intermingle in varying proportions.

**Statistics of Immigration** — The immigrants arriving in the United States are largely adults. The figures published by the Commissioner-General of Immigration show that of 9,555,673 immigrants in the years 1889 to 1910, 8,398,624 or 87.9 per cent, were over fourteen years of age. How widely this proportion departs from a normal age distribution of the population can be seen from the fact that in 1900 among the native whites only 61.1 per cent were over fourteen years of age.

The figures cited show the predominance of the adults among the immigrants. The following table shows the races which in the fiscal years ending June 30, 1899, to June 30, 1910, have contributed to the immigration to the United States. For convenience of reference the proportion of persons over fourteen years of age and the proportion of males and females have been added: —

# IMMIGRATION AND EDUCATION

IMMIGRANTS FOR YEARS ENDING JUNE 30,  
1899 TO 1910

RACE OR PEOPLE	TOTAL NUMBER OF IMMI- GRANTS	PER CENT		
		Male	Female	Over 14 Years of Age
African (black)	33,630	62.2	37.8	89.7
Armenian	26,498	76.5	23.5	88.8

Syrian	56,909	67.9	32.1	84.1
Turkish	12,954	96.3	3.7	97.8
Welsh	20,752	65.1	34.9	82.3
West Indian (ex- cept Cuban)	11,569	57.8	42.2	86.3
Other peoples	11,735	92.0	8.0	95.5
Not specified	77	76.6	23.4	87.0
Total	9,555,673	69.5	30.5	87.9

In the entire number here given the non-English-speaking races predominate. They constitute an aggregate of 8,549,741, or 89.5 per cent of the total. There is quite a contrast between these figures and those of the census in which we find reflected the influence of the older immigration. The earliest distribution of the foreign born by countries of birth is in the census of 1850. In this census there were enumerated 2,244,602 persons of foreign birth, of whom 756,079, or 33.8 per cent, were from non-English-speaking countries. On the other hand, the provisional figures of the census of 1910 show that of 13,342,500 foreign whites 9,571,700, or 71.7 per cent, are from non-English-speaking countries. In other words, recent immigration is bringing to our shores an increasing number of persons who do not know our language.

# IMMIGRATION AND EDUCATION

**Schools for Adult Immigrants**—So far as these persons are adults, and most of them are, the schools can as a rule help them to a knowledge of English only in so far as they show themselves willing to avail themselves of the opportunities which the evening schools afford. Originally established for the benefit of persons who had had no early opportunities for an elementary education, our evening schools no longer serve to any large extent to educate the native population in the three R's. Besides the higher grades and high school work maintained for those who wish to continue an education already begun, they serve principally to teach the English language and a few rudiments to foreigners. No comprehensive investigation has yet been undertaken as to the extent to which this service is being rendered by the evening schools of the country.

NUMBER OF IMMIGRANTS TO THE UNITED STATES 1892-3 TO 1910-1911 OF FOURTEEN YEARS OF AGE AND UPWARD, TOGETHER WITH THOSE UNABLE TO READ AND WRITE

From Reports—Bureau of Immigration

FISCAL YEAR ENDING JUNE 30	TOTAL	UNABLE TO READ AND WRITE	
		Number	Per Cent
1893	1,359,153	2,61,038	17.0

<sup>1</sup> Fifteen years and over

<sup>2</sup> Seventeen years and over

<sup>3</sup> See notes <sup>1</sup> and <sup>2</sup>

A few illustrations drawn from school reports of larger cities will show the importance and extent of this service which is rendered to the foreigner by the evening schools. In New York City in the school year 1909-1910 there were 80,369 pupils enrolled in the elementary evening schools, and of these 33,436 were foreigners learning English. In Newark in the same year there were 9135 pupils enrolled in the evening schools of elementary grade. Of these 3055 were in classes for teaching English to foreigners. The superintendent estimates further that among those in other evening schools a large proportion, certainly over one fourth, were

# IMMIGRATION AND EDUCATION

NUMBER AND PER CENT OF IMMIGRANTS ADMITTED TO THE UNITED STATES WHO WERE FOURTEEN YEARS OF AGE OR OVER AND WHO COULD NEITHER READ NOR WRITE, DURING THE FISCAL YEARS 1899 TO 1910, BY RACE OR PEOPLE

<sup>1</sup> Including 693 " Hungarians " in 1899

<sup>2</sup> Including 35 " Hungarians " in 1899

of foreign birth In Jersey City in an enrollment of 2240 in evening schools 1122 were of foreign birth In Philadelphia in a total registration of 12,230 in elementary evening schools 6354 were of foreign birth Chicago in the school year 1907-1908 had 20,133 enrolled in all its evening schools, and among them were 12,344 in the foreign classes and 1267 other persons of foreign birth in other classes. There are also a very few interesting day classes

# IMMIGRATION AND EDUCATION

for foreign adults, which are frequented by persons, such as watchmen, who pursue their regular callings at night

**Illiteracy among Immigrants.** — The problem of the immigrant is not only one of language, but of general education. Unfortunately we possess no generally accepted standards by which education can be statistically measured, except for such slight minimum of education as is represented by the ability to read and write In the absence of other measures, this becomes important. It is a familiar fact that the immigrants do not measure up to the standard of literacy which prevails in the nation at large, and especially in the white population. The table on the preceding page summarizes by years the illiteracy of immigrants

There is in these figures no evidence of improvement during the period, but rather the reverse This change may be due in part to the shifting of the character of immigration. In this connection the table of illiteracy by races which precedes is of interest

An examination of this table reveals great diversity. Many of the races here represented show a less degree of illiteracy than was found in 1900 in the native white population of the United States (4 64 per cent) Others show a much larger percentage, which in several cases represents more than half the immigrants Some of the races represented in the table have been coming to the United States in greater or less number for many years These are the Dutch, English, Flemish, French, German, Irish, Portuguese, Scandinavian, Scotch, Spanish, and Welsh The remainder are comparatively newcomers Designating the former for convenience as the old and the latter as the new immigration, we have the following results as to illiteracy among the two classes in the period 1899 to 1910

## ARRIVALS 1899-1910, FOURTEEN YEARS OF AGE AND UPWARD

	TOTAL	ILLITERATE	PER CENT ILLITERATE
Old	2,122,282	103,948	4 9
New	6,276,342	2,134,863	34 0
Total	8,398,624	2,238,811	26 7

It would be a mistake to assume from these figures that immigrants are necessarily more illiterate than formerly They merely show that if immigration came to-day from the same countries as formerly there would be less illiteracy than at present In 1850, 42 per cent of the foreign born were Irish Ten years earlier, in 1841, the Irish census ascertained the fact that 53 per cent of the population were illiterate Hence we may infer that the illiteracy of the immigrant was as great sixty years ago as it is to-day.

## IMMIGRATION AND EDUCATION

The statistics of illiteracy among immigrants are in part borne out by the census figures for the illiteracy of the foreign born. The census figures are as follows. —

CENSUS	PER CENT ILLITERATE
1880	12 0
1890	13 1
1900	12 9
1910	12 8

The wide difference between these figures and those of the immigration authorities might be accounted for on the supposition that the older immigration had less illiteracy, and hence the percentage was less among the foreign born, with its many representatives of this class, than among the recent immigrants. As we have seen, this position is hardly tenable. The explanation may be in part that among the birds of passage who come and go there are more illiterates than among those who permanently remain in this country.

It is clear from the consideration which has already been given to the ages of the immigrants that the public school can do little toward reducing this illiteracy. Only a small proportion of the immigrants themselves come perforce under the operations of the school system, since relatively few are under fourteen years of age, the usual limit of compulsory school laws. Night schools can, as we have seen, do something, but their influence is limited. Those who in the struggle to get a foothold yet find time to avail themselves of the opportunities such schools afford, are for the most part those who have a reading knowledge of their own languages. Before considering the question of the relation of the schools to the small class of child immigrants, we may inquire how far the illiteracy of the immigrant and of the foreign born tends to perpetuate itself in the second generation.

### Illiteracy among Children of Foreign Parents.

— On this point the census enumerations bear gratifying testimony. The native whites of foreign parents have a smaller percentage of illiteracy than the native whites of native parentage. The testimony of the census of 1900 was as follows. —

NATIVE WHITE.	PER CENT ILLITERATE	
	North Atlantic	North Central
Native parents .	17	28
Foreign parents .	15	13

Instead of figures for the United States, those of the divisions where the foreign element is most numerous are given in order that the two groups may be compared under circumstances as nearly as possible identical. In each case the proportion of illiteracy is gratifyingly small, but it may be noted that in each group of states

## IMMIGRATION AND EDUCATION

mentioned it is less for the persons of foreign than of native parentage. This apparent advantage in favor of the foreign element is due to the fact that they are more largely city dwellers than the pure native stock, and enjoy on the whole better educational advantages. If the two groups be compared in the same localities, as, for instance, in the cities, there appears a slight advantage in favor of the purely native stock, though, as already noted, the amount of illiteracy for either class is insignificant. In the disappearance of the difference as respects illiteracy between native and foreign elements in the second generation we have indirect evidence of the service of the schools in assisting in the assimilation of the immigration.

**Schools and Young Immigrants** — We may now return to the question, what can the schools do for the child immigrant? This manifestly depends upon the age of the child, which determines the length of time which it will stay under the school influence. If the child is under school age at the time of its arrival in the United States, it enters the school with little more handicap than children of the same race who are born in this country. If, on the other hand, the child is twelve years old when it comes here, it is not likely to have more than two years' schooling.

Just how the children arriving in the United States are distributed as to ages is not apparent from the statistics of immigration. An investigation conducted by the Immigration Commission in twelve different cities in the United States showed that of 38,254 children having foreign fathers there were 8724, or 22.8 per cent, born abroad. Of the latter information was available as to the age of arrival in the United States, as follows: —

AGE	NUMBER	PER CENT
Under six years	4785	57 1
Six and seven years .	1647	19 7
Eight and nine years	1108	13 2
Ten years and over .	838	10 0
	8378	100 0

It appears that more than half the children had not yet reached the age of school attendance.

For the older child the problem of the public school is largely one of language rather than of general education. How can these children be taught to understand what is going on around them in the school? Where they are few in number the common expedient is to put them into the first grade and hope that they will gradually be able to take part in the school work. This is largely leaving them to work out their own salvation, but it places them in favorable position to do so. It introduces them to the English language in its simplest

forms, as the vocabulary of the teacher in first-grade instruction is of necessity limited to simple words and is combined into simple sentences. Better results are obtained when it is possible by reason of their number to place these pupils in a special class under a teacher skilled in teaching them English and awaiting a certain proficiency in English, before assigning them to the regular grades. Such classes are a regular feature of many school systems of our cities with a large immigrant population. The obstacle to the generalization of this system is that there are not enough children of this description in each of the schools to constitute special classes. This is in practice largely overcome by the habit of the immigrants of settling in definite localities in the cities where they find others of their race.

**Special Classes** — In New York City, where the special classes for foreigners are highly developed, the foreign-born child of eight years of age or under is usually placed in the regular grades, the special classes being considered necessary only for older pupils. With upwards of 600,000 pupils in the elementary schools of New York City in 1900, there were 1240 in these special classes. Cincinnati gives to the newly arrived children who are nine years of age or over training especially in English. One class suffices for the city. It is obvious that the needs of the older immigrant child, however important to the individual himself, do not present a problem of such magnitude that it taxes in any way the resources of the school system.

For the younger immigrant child, who was brought here by his parents as an infant, and who enters school at the same age as other children, the problem of language is of no special significance. It is not infrequently supposed that the language problem is the most serious one in the education of the child of foreign parents. The experience of the schools so far as the younger children are concerned, refutes this view. The foreign child who enters the first grade, or better still the kindergarten, has no unusual difficulty. The language of the schoolroom is so simple that its comprehension is readily acquired and the child advances at an equal pace in his knowledge of English and his studies. It is understood that in the Philippine Islands no difficulty is encountered in teaching in the English language, and the writer had a like experience in conducting the schools of Porto Rico. In these instances English is used as a medium of instruction when there is far less English as a background in the environment of the child than in our American cities. It is not contended that for these very young children an ignorance of English is not a factor of some importance. But its importance consists not in a direct impediment to the progress of the child, but in its significance as an indication of a home environment unfavorable to the school progress of the children.

**Native Children of Foreign Parents.** — Our discussion of the relation of the schools to the immigrant children has brought us by natural stages to the consideration of a group among them, in which the fact of foreign birth has little significance except as it involves foreign parentage. There is in fact little difference ten years later between the child who was brought into this country as an infant in arms and his one or two years younger brother or sister who was born in this country. We may therefore now inquire as to the relation of the schools to children of foreign parentage.

The native children of foreign parentage in our schools represent the offspring of many races, which may or may not vary from the native white American in language, but are supposed to vary to at least some extent in traditions, ideals, and aspirations. Such differences appear, so far as the record goes, to have had little effect in perpetuating among the second generation that great degree of ignorance which we term illiteracy. It may, however, be that if we could establish some higher standard of proficiency it would be seen that there was some divergence between the progress of children of native as compared with foreign parentage. Considerable light can be had on the problems of school advancement by a study of the facts of grades and ages of the pupils, and especially of the relation of the two expressed in the now familiar concept of retardation (*q v*). The investigations of the Immigration Commission in 1908 conducted by the writer, the results of which have been only partially published, cover a wide range, embracing a study of pupils in thirty-seven different cities. These investigations distinguish pupils by parentage determined by the race of the father. The contrast which here concerns us is between white children having fathers born in this country, and those whose fathers were born abroad. In the latter group are included native whites of foreign parentage, the predominant element, and foreign white, but as we have already seen, the last-named are comparatively few in number. It would exceed the limits of space to give anything more than a few brief notes of the main results of this investigation.

PUPILS IN SCHOOL AT EACH AGE FOR 1000  
AT AGE OF NINE YEARS

CHILDREN OF	5 YEARS	6 YEARS	7 YEARS
Native fathers . .	84	733	943
Foreign fathers . .	89	772	934

The figures for the ages are used to establish certain probabilities in regard to entering and leaving school. Pupils in school in the early ages are compared with the estimated number at nine years of age computed by taking the average of those reporting the three ages eight,

## IMMIGRATION AND EDUCATION

nine, and ten years. The results in proportions are given on previous page.

In like manner we can compare the older children in school with the computed number at the age of eleven.

PUPILS IN SCHOOL AT EACH AGE FOR 1000 AT AGE OF ELEVEN YEARS

CHILDREN OF	13 YEARS	14 YEARS	15 YEARS	16 YEARS	17 YEARS	18 YEARS
Native fathers	963	769	503	297	173	136
Foreign fathers	959	665	333	145	71	57

These parallel figures show clearly that there is very little difference between the children of native fathers and those of foreign fathers with respect to their early entrance in the schools. There is, however, a smaller representation of the children beyond the school age among those whose parents are foreign than among those whose parents are native. Such a smaller representation might be due in the case of individual races to the fact that in these ages there were fewer children in the community. But with respect to the children of foreign parentage as a whole, such an explanation is not valid, and the more obvious one that children of this class drop out of schools sooner than those whose parents are native applies.

Confirmation of the conclusion that the children of foreign parentage leave school at an earlier age than those of native is found in the following figures, which distribute the children among the different schools.

PER CENT OF ALL PUPILS IN DIFFERENT KINDS OF SCHOOLS

CHILDREN OF	KINDER- GARTEN	PRIMARY	GRAMMAR	HIGH SCHOOL
Native fathers	4.3	52.1	34.5	9.1
Foreign fathers	4.4	57.6	33.3	4.7

It will be noted that in the grammar and high schools where the children are of older age the proportions are less for the children of foreign parents than those of native parents.

With respect to the progress of children within the schools, we have a convenient measure in the concept of retardation. This is calculated in the following ratios for all elementary pupils and also for those pupils who are ten, eleven, and twelve years of age.

PER CENT OF PUPILS WHO ARE RETARDED

CHILDREN OF	ALL ELEMENTARY	PUPILS, 10, 11, AND 12 YEARS OF AGE
Native fathers	34.1	42.0
Foreign fathers	36.0	46.2

## IMMIGRATION AND EDUCATION

By both methods of calculation it appears that the retardation of the children of foreign parents is somewhat greater than those of native parents, but the most remarkable result of these investigations is not that the difference is so great, but that the difference is so small. In other words, this investigation confirms in general terms the showing of the census that so far as intellectual attainments are concerned any difference between the native and the foreign stock practically disappears in the second generation.

It is to be noted that in the foregoing percentages in the investigation of the Immigration Commission we are dealing with the pupils of foreign stock, and not merely with those of foreign parentage. Had the investigation eliminated the children of foreign stock who were born abroad, it is more than likely that even the small differences which have been observed would disappear in the contrast between the children born in the United States of foreign parents compared with those born of native parents. In a more limited investigation undertaken by the commission, where it was possible to make this distinction, there were a number of cities in which the retardation of the children born in the United States of foreign parents was even less than that of purely native children.

This special investigation brought out clearly the fact that the language inherited by children of foreign birth was not in itself a serious obstacle to the progress of children in American schools. The backwardness of the foreign child and the child of foreign descent, so far as it is established by this investigation, appears as a result of various conditions of home life which are unfavorable to the best progress of the children in the school. However great the duties which immigration creates for the administration of schools in the United States, the records show that the schools have in large degree mastered those duties and have contributed in no small measure to the gradual process of assimilation by which the foreign elements are merged into the body of the American people.

## IMMUNITIES

Much periodical literature will be found under the title *Immigration*, in Poole's *Index to Periodical Literature* and in the *Readers' Guide to Periodical Literature* (Cumulated)

**IMMUNITIES.** — See EXEMPTIONS, SCHOOL MANAGEMENT.

**IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY** — See LONDON, UNIVERSITY OF.

**IMPRESSION** — A general word referring to sensory mental processes. Thus one receives a visual impression from a bright object, an auditory impression from a source of sound. Practically synonymous with the word "sensation" In ordinary parlance, the word is used with a somewhat more general sense to refer to striking experiences as well as simple sensory processes  
C. H. J.

See SENSATION.

**IMPRESSION** — In Method — The traditional methods of teaching in the lower schools have been for the large part dogmatic and authoritative. They called for a receptive attitude on the part of the child, rather than one which is active. There is, however, a vigorous reaction expressing itself against such modes of procedure. Its effects are noted in the effort to introduce subjects which call for increased motor and mental activity upon the part of the child, thus manual training, singing, drawing, and play have grown in favor. A similar effect is found in the domain of teaching method. Teaching the children to study rather than merely to memorize is a movement toward the development of a larger initiative in the pupil. Dramatization and "action work" as modes of instruction are other influences suggesting increased emphasis by the modern teacher on the self-activity of the child. The popular pedagogical phrase, "No impression without expression," summarizes the modern psychological attitude toward instruction.  
H. S.

See TEACHING, PRINCIPLES OF; MOTOR ACTIVITY

**IMPULSE** — Activity which is not preceded by deliberation, which follows immediately upon an external impression and is consequently likely to be relatively unintelligent, is described as impulsive. The term "impulse" is used not only for the above described type of activity, but it is used as a general term to indicate any tendency on the part of individuals toward definite lines of action. That is, there is a general impulse toward imitation (*q.v.*), an impulse toward self-preservation. (See INSTINCT) Impulsive activity is characteristic of undeveloped individuals. The savage is impulsive in his activities rather than deliberate. The child is impulsive.

**INCENTIVES.** — See REWARDS AND PUNISHMENTS, also ATTENTION; INTEREST, MOTIVES; SCHOOL MANAGEMENT.

**INCEPTION.** — (Latin *incipere*, to begin, commence) The ceremony of admission to the rank or grade of master or doctor in the medieval universities. With it was connected the entrance on the teaching career by actual performance of duties pertaining to it. Two influences may be traced in the ceremony of inception: (1) Of Roman law, "according to which a man was invested with the *de facto* possession of his office by an actual and solemn performance of its functions" (Rashdall), and (2) the guild initiation of a master by older members, and possibly the ceremony of investiture of a knight. The ceremony at Paris University was performed in the schools of the respective faculties, and consisted of the placing of the cap or *biretta* on the candidate's head and the granting of the ring and the book by his former master, who also conferred on him a kiss and a benediction. The inceptor was then placed in the master's chair and delivered a lecture or held a disputation. The expenses of the ceremony were considerably increased by the custom of making presents to the older master, of contributing to the society's funds, and of giving a banquet to the new colleagues. Inception became in time more important than the Chancellor's license to teach, and corresponded in every way to the compulsion to belong to a guild before a trade or craft could be practiced.

The inception or *principium* was common in Paris and the northern universities, at Bologna the corresponding ceremony or public examination was known as the *conventus*, which was conducted in the cathedral and was more elaborate and expensive than at Paris. (Compare the use of the term commencement (*q.v.*) for the graduation ceremonies in American universities.)

See DEGREES; UNIVERSITIES.

**INCIDENTAL EDUCATION.** — It is held by some that a certain mental capacity can be trained without explicit attention to this particular faculty. Thus, if we carry on a course in history, there may be an incidental training of the moral sense. The possibilities of leaving certain phases of education to be taken

## INCIDENTAL METHOD

care of in a secondary way in connection with major forms of training has been much discussed. It would be economical, if we could relegate the training in reading to the science class, devoting the major attention in this class to the subject matter, and yet securing incidentally for the children the ability to use language. A distinction of importance should undoubtedly be made in these discussions. A certain type of training may be incidental from the point of view of the child, but explicit and primary from the point of view of the teacher. On the other hand, a certain type of training may be incidental both for the teacher and for the child. In this latter case the training which is treated as incidental is likely to be neglected altogether. In the former case, while the child regards himself as working for a given end, he may be induced through skillful guidance to carry on a variety of activities which will conduce to training in a number of different directions. The secondary lines of training are incidental in this case only for the child, not for the teacher. C. H. J.

See FORMAL EDUCATION; FAMILY EDUCATION.

**INCIDENTAL METHOD** — Any plan calling for the teaching of a series of facts, forms, or skills incident to the systematic study of some other subject utilizes the "incidental" method of teaching. Arithmetic, spelling, and grammar are among the subjects that are sometimes taught incidentally. Thus if arithmetic is not taught systematically as a subject till the third school year, it is taught incidentally during the first two years, that is, such arithmetical facts are taught as occur in the normal experience of the child or within the other school subjects. Again, those who propose that the subject of grammar should not be taught as a separate subject suggest that its important and useful facts might be taught as mere incidents of written composition. A still further instance is found where it is urged that spelling should be discontinued as a subject with the close of the sixth school year and taught incidentally thereafter.

H. S.

See METHODS, TEACHING

**INCIDENTAL PERIOD.** — In arranging the school program it is the practice in some schools to leave certain class periods unassigned to a specific activity, such as a recitation in arithmetic or a study period in history. These hours are termed "free" or "unassigned" periods, and are utilized by the teacher only as special need occurs, such as the need to bring up a class in language, or to render additional assistance to individuals who are behind in their work. Because of the use of such time for incidental needs that arise in the course of the regular teaching, they are termed "incidental periods".

H. S.

## INDETERMINATE EQUATIONS

**INCOHERENCE.** — See SPEECH DEFECTS

### INCOMMENSURABLE QUANTITIES —

Quantities that have no common measure with a quantity arbitrarily taken as the unit. For example, if the side of a square is taken as unity, the diagonal of the square is incommensurable with it, and numerically it is represented by  $\sqrt{2}$ . The number  $\sqrt{2}$  is called an incommensurable number, there being no integer or common fraction that will exactly divide it and unity. Incommensurable numbers have of late been the subject of extended study, notably by Dedekind and G. Cantor.

From the standpoint of the secondary school, the interest in incommensurable numbers and magnitudes centers in the work in radicals in algebra and in the so-called "incommensurable cases" in geometry. The scientific study of incommensurable numbers is so recent that no attempt has been made to introduce the modern theory into elementary algebra. On the other hand, the study of incommensurable lines, surfaces, and volumes found place in Euclid's *Elements*, and hence it still appears in many textbooks in plane and solid geometry. A popular treatment of the subject from the numerical standpoint would be quite as easy as one that relates to geometry. It is, however, the growing opinion that the concept is too abstract for the immature mind of the high-school pupil. The treatment of the subject in the current geometries is not scientific, and, since it is merely a popular introduction to the theory and is understood by a relatively small number of pupils, it is, at the present time, passing out of the high-school curriculum in the United States. It is felt that its place is in the calculus, where the theory of limits is treated with some approach to scientific rigor. It is entirely proper, in the secondary school, to speak of the incommensurable, both in algebra and geometry, explaining its general nature. Any serious attempt at a scientific treatment of the subject is, however, out of place at this point in the pupil's education.

**INDEPENDENT WORK.** — See SCHOOL MANAGEMENT.

**INDETERMINATE EQUATIONS.** — An equation is said to be indeterminate when there are indefinitely many roots that satisfy it. For example,  $x + y = 4$  is satisfied by the following pairs of roots (0, 4), (1, 3), (2, 2), (3, 1), (4, 0), (5, -1), and so on indefinitely, and by an infinite number of non-integral roots,

such as  $(3\frac{1}{2}, \frac{1}{2})$ ,  $(7\frac{1}{2}, -3\frac{1}{2})$ , and  $(\sqrt{2}, 4-\sqrt{2})$ . A system of equations is indeterminate when there are indefinitely many roots that satisfy each and every one of the equations. In general, if there are  $n$  equations and  $n+1$  unknown quantities, the system is indeterminate. The subject of indeterminate equations, particularly of the second degree, was first studied extensively by Diophantus ( $qv$ ), and hence such equations are often called Diophantine equations. An indeterminate equation may have only a limited number of positive integral roots, as in the case of  $x+y=4$ , or it may have an unlimited number of such roots, as in the case of  $x-y=4$ . In the older textbooks on algebra the former of these two kinds of equation often appeared, with the direction that the equation was to be solved in positive integers. At present, so crowded has the course in elementary algebra become, the subject plays practically no part in the work preparatory to the American college, although it is found occasionally in the college course. Since it does not lead to any other theory of much importance, it is generally felt that the time which an extended study of the subject would require may better be devoted to other work. The subject of alligation ( $qv$ ) is an early phase of this one, representing a crude form of indeterminate analysis applied originally to questions of the mixing of metal in coinage.

Aside from the general subject of indeterminate equations, there is the special question as to when an equation or a system of equations is determinate, and this properly forms a significant topic in elementary algebra. In this connection the graphic representation of an equation is helpful.

As an example of an indeterminate equation of the second degree, suppose two positive integers are to be found such that if their product is taken from the sum of their squares the difference shall be a square. In other words, required to solve the equation

$$x^2 + y^2 - xy = \text{a square, say } z^2,$$

in positive integers. The equation is satisfied if  $x = 2mn - n^2$ ,  $y = m^2 - n^2$ ,  $z = m^2 - mn + n^2$ , and special solutions may be obtained by substituting any positive integers for  $m$  and  $n$ , with the limitation that  $m$  shall be greater than  $n$ .

D E S

**INDETERMINATE FORMS** — Certain quantities met in algebra are in forms such that it is frequently impossible to determine their value. For example,  $\frac{0}{0}$ ,  $\frac{\infty}{\infty}$ ,  $\infty^0$  are such forms. In the secondary school such expressions are properly avoided, being relegated to the calculus where they have place. When met in elementary algebra, as in the case of  $(a-b) \div (a-b)$  when  $a=b$ , they are best

passed over without reference to the fundamental principle of limits that is involved. It is sufficient, when the symbol  $\frac{0}{0}$  arises in the interpretation of a problem in elementary algebra, to say that  $a \cdot 0 = 0$ , where  $a$  is any finite number; whence, if we think of 0 as being admitted as a possible divisor, we have  $a = \frac{0}{0}$ . It is therefore reasonable to define

the form  $\frac{0}{0}$  as standing for indetermination.

While not satisfactory as a scientific proof, this simple explanation of the reasonableness of the definition is sufficient for elementary algebra.

**INDEXES** — See BIBLIOGRAPHIES OF EDUCATION.

**INDIA, EDUCATION IN.** — **Political Organization of the Empire.** — Strictly speaking, the term British India applies only to the divisions under direct British administration, and does not include the native states which are indirectly under British rule. The native states have independent control of their educational affairs, but they are rapidly adopting the system developed for British India. For purposes of administration, India is divided into nine great provinces, namely, Madras, Bombay, Bengal, Eastern Bengal, and Assam, united provinces of Agra and Oudh, Punjab, Central Provinces, Northwest Frontier Provinces, and Burma. There are also the following minor charges: Coorg, Ajmer-Merwara, British Baluchistan, and the Andaman Islands. Each of the nine provinces is under the administration of a governor, or a lieutenant-governor. The governors of Madras and Bombay are appointed by the Crown; the remaining chief officers are appointed by the Governor-General with the approval of the Crown. The minor charges are each under a chief commissioner.

Each province is usually broken up into divisions under commissioners, and these, again, are divided into districts — numbering in all about 259 — which are the units of local administration. The supreme executive authority in India is vested in the Governor-General in Council, often styled the Governor of India. He is appointed by the crown, and usually holds office for five years. The control of the Governor-General extends to all the provinces, but they enjoy a large degree of administrative independence varying with their importance. The local government of British India is vested in municipal boards, the members of which are, in large majority, elected by the ratepayers (Acts of 1882-1884). For rural

tracts, there are district and local boards which are in charge of roads, district schools, and hospitals

The area of the British provinces is 1,097,901 square miles, the population (census 1901), 232,072,832, the average population per square mile, 211. The area of the native states is 690,272 square miles, the population (census 1901), 61,325,376, population per square mile, 189. The totals for India are, then: area, 1,766,642 square miles, population, 294,361,056, population per square mile (census 1901), 167. The total as given in census of 1911 is 320,132,537.

**Ancient Systems of Education** — *The Hindu System*. — The endeavor of the British government to engraft a system of modern education upon its Indian Empire is impressive by reason of the enormous population dealt with, and the character of the native civilization and culture. From time immemorial India has been a land of schools, of literature, and of philosophy, inseparably associated with the religions which dominated its people before the advent of the English, and have profoundly affected the course and progress of education under their auspices. The first of these, the Hindu religion, gave to the land the Vedic literature, the Brahmins or priestly class, and the caste system, in other words, all that has proved vital and permanent in Hindu higher education.

The Vedas reveal the religious ideas and the movement of this Aryan people from the time they began their invasions of India, swept onward from the Indus to the Ganges, overcame or scattered the indigenous tribes, and eventually organized kingdoms each under its own ruler, but all dominated by the powerful priesthood.

In the absence of chronological records, all dates in the early history of India are inferences chiefly from the Hindu language and literature; but it is generally agreed that the Brahmanic period began about 500 B.C. and continued with little abatement of power to the thirteenth century of our era. The Brahmins were the priests, teachers, and lawgivers of the people, the custodians of the Vedic hymns and authors of the whole body of literature based upon them — the mythologies, rituals, commentaries, and laws — for all of which they claimed divine sanction. This sacred literature, together with heroic, secular poems and a crude science, also of Brahmanic origin, were the substance of Hindu higher education. The Brahmins determined the limits of knowledge for the castes below themselves, the *Kshatriyas* (warriors), the *Vaisyas* (husbandmen), and the *Sudras* (artisans and traders). Below the *Sudras* was an undefined mass of people, the indigenous tribes, low-down Aryans, and mixed peoples, indiscriminately termed *Pariahs* (outcasts). For these there were no rights nor privileges, and no instruction excepting what filtered down through the

all-pervading religious ceremonies — incantations, sacrifices, and idol worship — still maintained in parts of India.

On account of the difficulties of Sanskrit, the language of the Vedic literature, the Brahmins had a practical monopoly of learning, the majority merely learned by rote the hymns and prayers and ritual used in the religious ceremonies, leaving to the few that lifelong absorption in learning which was one condition of attaining supreme bliss.

The sacred obligation to teach, laid upon every one of the higher caste, was accomplished in general by oral instruction, which imparted to the privileged the religious ideas and caste obligations that made up the chief concern of life. As the social organization developed, there gradually grew up separate schools of literature, of law, of Vedanta, and even separate schools of astrology or astronomy and of medicine.

While the Brahmanic or Sanskrit schools of learning reached but a small fringe of the immense population, the village school had a much wider range. It was an integral part of the village life, which, like the caste system, illustrates the organizing genius of the Brahmins. The soil, chief source of wealth in that agricultural land, was controlled by the community, though not to the exclusion of private ownership. The civil offices — headman, accountant, priest, schoolmaster, etc. — were hereditary in families, and carried for the incumbent an allotment from the village land. The various industrial arts, carpentry, pottery, weaving in cotton and silk, leather work, stone cutting, and the higher arts fostered by royal luxury and by the religious ceremonies, — architecture, sculpture, and the goldsmith's art, — were also hereditary. The craftsman, like the civil officers, had his allotment of the village lands, and he was, moreover, a member of a guild which had rights and obligations of its own. Thus industrial art was a product of family training.

The village school (*pathshala*), like the village itself, was founded on the sanction of the *Shastras* (books of sacred laws). In its primitive form it was a mere class of village boys from five years of age to ten or twelve years, sons of petty landowners, traders, and cultivators, assembled around the master, under a spreading tree or in a shed. The instruction was oral, and as each boy had his own task, the older pupils taught the younger. Tracing the letters on a sandboard with the fingers, and afterwards on the ground with a crayon, constituted the earliest exercises; later, words and sentences were written on palm leaf or on prepared wooden tablets, with a reed pen dipped in charcoal ink, the numeration tables, money, weights, measures, and simple accounts completed the course of instruction. In some parts of India, especially in the Punjab, there were attempts at regular gradation of

classes, and in the trading centers, there was a class of schools termed *Landé*, in which boys learned to write a special business character. The village schools, in which only the vernacular language was used, were entirely distinct from the Sanskrit colleges (*tois*). The former had an eminently practical aim; whatever formative influence they exercised was due to the personal character of the teacher, to the ethical maxims which were copied and recited, and to the stories and verses rehearsed to the pupils.

The Brahmanic system of caste and caste education in its full development was limited to the "middle land" of India; that is, to the region north of the Vindhya range comprising the river systems of upper India with their fertile valleys; but the village system and the religion of Brahma spread throughout India.

*Antagonistic Influences* — Every religious movement that subsequently developed in India was a reaction against Brahmanic domination, the tyranny of caste, and the monopoly of learning. Chief among these reactions was Buddhism, which prevailed over Northern India from the sixth century B C to the eighth century A D, when it was driven out of the Indian peninsula by the persecutions of the Brahmans. Buddhism left no schools in the land, but it struck at the heart of Brahmanism by its doctrines and its recognition of secular teachers. (See *BUDDHA AND BUDDHISM*.) A similar influence was exerted by the Sikhs, the Protestants of the Punjab, who arose in the fifteenth century, and whose schools remain to the present time.

*Mohammedanism* — The Mohammedan religion was introduced into India by an alien people in the eleventh century, and its power and permanence were assured by the establishment of the Mogul empire in the sixteenth century. The first revelation to Mohammed is contained in a single verse of the Koran: "Read in the name of thy Lord!" In obedience to this command, every mosque in India, like the cathedrals of Europe, had a school attached, in which children were taught the Arabic alphabet and selected verses of the Koran. In the higher schools, which were supported by imperial grants and private bounty, learned Mohammedans taught Arabic, the sacred language of the Koran, and Persian, the language of the royal circle and of the courts of law, where Moslem rule was established. To the study of language were added rhetoric, logic, literature, law, and crude science. All students were welcome, and the Persian schools became a common meeting ground for Hindu and Moslem youths, even women were not ignored in the scheme of universal instruction.

The Moslem teachings operated as an organizing influence among the outcasts and the aboriginal tribes, and at the same time they

modified the rigid caste notions of the Brahmans themselves. As a consequence, many treasures of Vedic literature were translated into the vernaculars.

At the advent of British rule in the seventeenth century the population of India was comprised substantially in the two great bodies, Hindus and Mohammedans, in about the proportion of four to one. In this comparison aborigines, who in 1872 numbered five and a half million in a total of 191,096,603, are not included. Unlike as were the principles of the two systems, the effects of their intellectual disciplines were similar. Both gave excessive development to the memory and fostered a passion for abstract reasoning, qualities which must be kept in mind in the endeavor to estimate the progress of Western education in the empire. Schools of both systems, in number about 40,000, are still in operation, as shown by the government reports. Many of the old village schools have been transformed into modern primary schools, and a few Sanskrit and Persian higher schools partially transformed into modern colleges.

As to the existence, general character, and wide diffusion of the ancient schools, all authorities agree; but no statistical measure of their operations was attempted before the English occupancy. Investigations carried on in three presidencies, Madras, Bombay, and Bengal, between 1823 and 1835, showed about the same condition in all. The most complete of these investigations was made in Bengal by Mr W Adams, who reports 3355 schools with 41,247 pupils in a population of 7,789,189. Mr Adams estimated that of the adult male population about 5.55 per cent could read and write.

*The Transition Period* — The British East India Company was incorporated by the British Government in 1600, under the title of the Governor and Company of Merchants of London trading in the East Indies, and soon after received the charge of Bengal from the Emperor of Delhi. During the first century of the Company's operations nothing was done in regard to education in their ever-increasing domain. The work was begun by missionaries, who followed the traders early in the eighteenth century, and for a hundred years more the record of English educational effort in India is solely that of missionary zeal reinforced at a few points by private undertakings. No action was taken by the government in the matter until 1813, when, upon the renewal of the East India Company's charter, a clause was introduced providing for an annual expenditure of 100,000 rupees (equivalent at that time to \$50,000), by the Company's Court of Directors, for education in India. The appropriation was expended largely in scholarships to enable promising students to attend the existing schools, and for some time the government merely supplemented mission-

ary and private agencies with a constantly increasing effort at their organization. The entire period, from the beginning of the eighteenth century until the middle of the nineteenth, when the Indian government was charged with full responsibility for the education of the native population, may be regarded as a period of transition from ancient to modern conditions. It prepared the way for a general system of native education on European lines and under government direction. Two essential conditions of the system were worked out in missionary schools: the use of the vernaculars in the instruction of the masses, and the place of English in the scheme of higher education. The former was accomplished by the work of Carey, Ward, and Marshman in the Baptist mission at Serampore. These men, all oriental scholars of note, devoted themselves to the double task of teaching the humbler natives and translating modern textbooks into the languages familiar to Hindu and Mohammedan scholars. The question of English was practically settled by the action of Dr. Alexander Duff, who arrived at Calcutta in 1830 as the representative of the General Assembly of the Scotch Church. Ignoring all precedents, this energetic leader at once opened a school in Calcutta with the express purpose of making English the medium of instruction in the science and literature of Europe. The success of the school and Dr. Duff's articles on the subject, in the home papers, played a prominent part in the famous controversy of 1834.

While the mission schools were thus pushing forward on new lines, the private institutions established during this period — the Mohammedan College founded by Warren Hastings in Calcutta in 1780 and a Sanskrit College established in 1791 at Benares by a wealthy English resident — followed oriental models, and thus prevented a sudden and disastrous break between old interests and new purposes.

In 1823 the Indian government created a committee of public instruction to take charge of the annual appropriation for the work and of the institutions which had come under government control. These included one English and six oriental colleges, together with a number of elementary schools in Bengal. The committee became the organ of the government for education, and local committees were appointed to supervise the institutions that had the benefit of the fund, and to report to the central committee. In 1833 the annual appropriation was increased from 100,000 to 1,000,000 rupees (\$50,000 to \$500,000), after a hot debate over the question of the language to be adopted as the medium of higher education fostered by the government in India.

The opportune arrival of Lord Macaulay in India as the Legislative Member on the council of the Governor-General settled the controversy in favor of the English language. Ma-

caulay's Minute on the subject, bearing date Feb. 2, 1835, was followed by a proclamation issued by the Governor-General, Lord Bentinck, on the 7th of March of the same year, which declared that "the chief aim of the educational policy of Government should be to promote a knowledge of European literature and science." The use of the government grants in printing oriental books was discontinued, and the funds thus set free were thenceforth applied to promoting European studies through the medium of the English.

As a consequence of this decision English schools were opened in all the provinces. Hoogly College (Bengal), established in 1836, enrolled 1200 students, and an annex was at once provided. Statistics for 1843 gave a total of fifty-one schools and colleges under the government, comprising 8200 scholars. Of these 5132 were studying English. Moreover, Christian, Mohammedan, and Hindu boys, without regard to caste, came together, prompted by the common desire to learn the English language. The motive was obvious, the experience of centuries had taught the natives the advantage of knowing the language of their rulers, in the case of English, expectation was stimulated by the declared purposes of the government to admit trained natives to posts of importance. The principles laid down in Macaulay's Minute have never since been surrendered, but the claims of the classic learning of India were recognized in 1839 by a minute restoring for its maintenance an annual grant of 25,000 rupees.

During this period advance was made in all the provinces. In Bengal higher education received chief attention, in the Bombay Presidency the foundations of a public system of education were firmly laid by the vigorous action of Governor Elphinstone, in Madras native and missionary influences prevailed, in the Northwestern Provinces a model system of vernacular schools was developed through the endeavors of Mr. Thomason, the Lieutenant-Governor, in the Punjab, which did not come under the authority of the Company till 1849, a marked impetus was given to the indigenous schools and colleges.

Before the close of the period all the agencies of education, still at work in British India, missionary and private, municipal, provincial, and governmental, were fully established.

**The Government System — Departmental Period.** — In 1853, when the renewal of the East India Company's charter was under consideration, the feeling of the English nation, aroused to the responsibility for this distant possession, found free expression. In the year following the education of the whole people of India was assumed as a state duty, and the Court of Directors "laid down with fulness and precision the principles that were to guide the Indian Government in the performance of this great task." Their dispatch of 1854

forms the permanent charter of education in India. In a sense this celebrated document was simply the declaration of principles drawn from the experience of a century, and already formulated in Lord Macaulay's Minute and in orders issued by Lord Bentinck and Lord Auckland, acting in their capacity as Governors-General. But the Minute of 1854 gave to these principles the commanding sanction of the British government, and expressed the conviction and will of a nation. The main features of the policy thus announced were (1) the constitution of departments in the several provinces or presidencies for the administration of education, (2) the establishment of universities at the presidency towns; (3) the support of training schools for teachers; (4) the maintenance of the existing government colleges and high schools, and the increase of their number when necessary; (5) the establishment of new middle schools; (6) increased attention to vernacular schools, indigenous or other, for elementary education, (7) the introduction of a system of government grants in aid; and (8) inspection and periodical reports.

The instructions advised the largest freedom to local initiative, and insisted that government aid for education should supplement and be proportioned to the local expenditure. The importance of higher education was emphasized both in deference to the spirit of the people and as a means of preparing natives to enter in due proportion upon administrative and official careers; the importance of female education was urged, and as regards government institutions, it was ordered that the "education conveyed in them should be strictly secular."

Special reference was made in the dispatch to the need of colleges of medicine and civil engineering, and grants were authorized for schools of industry and design after the model of schools maintained by Dr Hunter at Madras, and by Sir Jamsetjee Jeejeebhoy at Bombay. The plan worked out by Dr Monat of the Bengal committee, for an agricultural division in each *zillah* or district school, was also endorsed. It was an all-inclusive scheme anticipating demands which have not yet been fully met in highly advanced nations, and which in India had necessarily to wait upon the slow disintegration of long-established institutions, customs, and prejudices.

In 1858 the East India Company ceased to exist and the government of India passed to the Crown. There followed the Dispatch of 1859, issued by the Secretary of State for India, which reiterated and confirmed the provisions of the earlier dispatch, with a single exception. The grant-in-aid system had failed to promote vernacular education, and it was declared that this purpose could only be realized by the direct action of the provincial governments.

*The Commission of 1882* — The system of

education, started under government auspices and aided by grants from the general treasury, was mainly dependent for its development upon the education departments of the several provinces. These departments naturally favored the interests of higher education, which course accorded with the prevailing native tendencies. For fifty years very little progress was made in the work of popular instruction; a mere fringe of the people in the immediate vicinity of the presidency towns was reached. Moreover, the select company of native students that passed through the schools and colleges, so far from helping to raise the average level of the nation, were drawn away from its vital concerns. The education problem was complicated, also, by other conditions fostered by English rule, especially as these had tended to exalt the Hindu race, the powerful Marathas of the south and the quick-witted Bengali, above their former masters, the Mohammedans. The menace of the situation was fully comprehended by Lord Ripon, Viceroy of India from 1880 to 1884, and in the second year of his administration he created a commission charged with the duty of examining into the educational system and advising as to the means of overcoming the dense ignorance of the masses and welding together the antagonistic races by common interests and sentiments. The Commission, which was remarkable both in its membership and its exhaustive methods, adhered strictly to the principles of the Dispatch of 1854, but urged as a matter of supreme importance the spread and financial support of primary education. For this purpose it was declared that native methods must be followed, particular attention paid to the education of women; the confidence of the Mohammedans secured; and the backward races brought under modern influences. The most important outcome of the labors of this commission was the increase of the central authority in the general direction of education. The change in this respect is indicated by the series of quinquennial reports on the progress of education in India issued under government orders, the first of the series covering the period 1881-1882 to 1886-1887, and by the creation in 1902 of the office of Director-General of Education in India.

*The Commission of 1904* — The resolution of 1904 was the outcome of special inquiries and conferences ordered by Lord Curzon, in view of unsatisfactory conditions disclosed by the third quinquennial report (1892-1893 to 1896-1897) on the progress of education. From this report it appeared that after a temporary advance, primary education was on the decline. The political development that had taken place since 1882 made the evil more alarming than at the earlier date, at the same time the relation of primary education to the entire system was more fully comprehended than ever before. The higher institutions had stimulated

an artificial craving for official life, and like the inferior schools had failed to reach the vital interests of the country, its industrial needs and social welfare. Hence the Resolution comprehended the whole system in a common criticism and called for reform in its conscious aims and formal processes. Special stress was placed upon the need of higher schools of agriculture and technical arts, upon instruction in science and its practical applications which foster observation and reflection upon natural phenomena as a feature of secondary schools.

The resolution voiced the convictions of many of the leading minds of the Empire, but it went far beyond the expression of opinion, and in no uncertain terms declared the purpose of the viceroy to employ all the forces at his command for the accomplishment of the proposed reforms. The sincerity of this purpose is indicated by subsequent reports. These ceased to be merely exhaustive summaries, and gave signs of vigorous activity. This is especially true of the series of occasional reports issued from the office of the Director-General. These deal with particular phases of education, point out defects, furnish suggestions, and follow instruction with the record of expert inspection. The effect is seen in the practical tendencies everywhere imparted to education and in increased appropriations for the work. The example is followed by native chiefs who are responsible for education in their respective states. In schools for princes conducted under the joint supervision of British and native authorities, these future rulers become habituated to western ideas and not only apply the educational system of the British provinces to their own states but in several instances set the advanced pace.

**Features of the System** — The reduction of the provincial reports on education to a unified scheme of statistical presentation was one of the chief outcomes of the Commission of 1882. Maintained by the subsequent quinquennial reports, this scheme makes it possible to grasp the common features of the system of education as it has worked out in the different provinces, and thus to form some conception of the state and progress of the work in spite of its magnitude and almost infinite variety of detail.

**Administration.** — The Director-General of Education in India has no authority over schools and colleges, the work of his office being that of general supervision and advice, made effective by his voice in the distribution of government appropriations for education. The provincial education departments administer the government appropriation and have general direction of public education in their respective divisions, and, in some cases, the direct management of public schools. As a rule, however, these are under the control of district, rural, or municipal boards. Departmental super-

vision is maintained by means of inspectors, of whom the larger proportion are recruited in England. The principals of the government colleges, and a certain proportion of the professors are also drawn directly from England.

By their examinations and the power of affiliating colleges, the universities have from the first controlled the system of higher education. Additional powers were conferred upon them by the Universities Act of Mar. 21, 1904, embodying the reforms proposed by the resolution issued by Lord Curzon. The act authorized the universities to institute regular inspection of the colleges and provide for their transformation into teaching bodies with power to make full provision for the promotion of study and research.

Colleges and secondary schools come within the sphere of university influence. The colleges are subdivided into (a) arts colleges, of which the majority are English, and a few oriental, and (b) professional colleges of law, medicine, and engineering. Their courses of instruction are regulated by the degree examinations. Secondary schools are subdivided into (a) high and (b) middle schools, the former teach up to the matriculation standard and are all English schools. The middle secondary schools may be either English or vernacular schools, the latter correlate with the primary schools and in the majority of the provinces are classed with them. There are also special schools, of which the most important are for training teachers, others are technical and industrial.

All schools and colleges recognized by the education department are classed as public, hence, the term applies to institutions established and maintained by public authorities, and also to those under private management which conform to the official regulations. The latter, which are established and conducted by religious or other associations, and also by private individuals, may be aided by public funds, or unaided and simply recognized.

It is necessary to have these distinctions in mind in order to understand the detailed statistics presented in the government reports, they are of interest also as illustrating the course of the English government in utilizing all the agencies of education and gradually bringing them into a well-ordered system. The distinction between institutions under public and those under private management may, however, be disregarded in a summarized statement of their operations.

**Sources of Income** — The expenditures for education are met by (1) provincial revenues, (2) local or district funds; (3) municipal funds, (4) fees, and (5) other private funds. Provincial revenues consist of that portion of general taxation allotted to a province which the local government devotes to education.

Local funds properly consist of that portion of local taxation which district or local boards devote to education. The system of local taxa-

## INDIA

tion varies greatly in the several provinces. In some cases there is a fixed cess, or rate, on agricultural lands for education; in others, a proportion of the general land tax (cess) must be devoted to education, in others, tolls and similar levies take the place of a land tax. Municipal funds simply consist of that portion of municipal taxation which is devoted to education. One of the features of the visit of the King-Emperor to India in 1911 was the announcement of a grant of fifty lakhs (\$1,666,665) "to the promotion of truly popular education." Further grants in future years are also promised.

**Operations of the System — Enrollment** — From the latest quinquennial report covering the period 1902 to 1907, it appears that the enrollment in all classes of institutions sustaining any relation to the government was, at the latter date, 4,744,480. If to this number be added the 644,152 students in schools known to, but having no relation with, the education department — that is, Arabic, Sanskrit, and indigenous vernacular schools, the grand total is 5,388,632, pupils and students. Disregarding the independent indigenous schools, the distribution of the pupils in the different classes of public institutions at the beginning and end of the period covered by the quinquennial report, and also for the later year 1908, is shown in the following table —

PUPILS BY CLASSES OF INSTITUTIONS

	1901-1902	1906-1907	Per cent of Increase	1908
Arts colleges	17,651	18,918	7.1	25,736
Professional colleges	5,358	6,250	16.6	
Secondary schools	622,768	713,342	14.5	754,267
Primary schools	3,204,436	3,937,866	22.9	4,190,14
Special schools	36,380	68,104	87.0	102,002
Total	3,886,493	4,744,480	22.0	5,708,238
Number in institutions under private management	2,646,852	3,088,513	16.6	
Number in institutions under public management	1,239,641	1,655,967	33.5	

**Relative Status of the Several Provinces in Regard to Education** — While the recent action of the central government of India has imparted vigor and unity to the educational work, it is, after all, an interest over which each province has independent control; hence, for an adequate conception of its development each province should be viewed separately. The following summary, covering the enrollment in all classes of institutions by provinces, may suffice to show the relative extent and vigor of modern education in each.

The statistics following fall into two groups: one pertaining to popular education as the term is generally understood; the other to the education of those classes from whom the directive forces of the Empire, the professions, the civil service, etc., are recruited.

## INDIA

PROVINCES	POPULATION	PUPILS IN PUBLIC INSTITUTIONS		Ratio of total pupils in 1906-1907 to population
		1901-1902	1906-1907	
Madras	38,210,362	740,628	875,666	2.3
Bombay	25,471,368	568,902	646,777	2.5
Bengal	52,669,869	1,548,022	1,215,014	2.3

<sup>1</sup> Assam only

The enrollment in primary schools is the natural index to the state of popular education in a country; but on account of the peculiar position of women in India, the number of girls in school must be disregarded in an estimate of general progress. The enrollment in schools for boys in 1907 was 3,631,000, equivalent to 20.5 per cent of the boys of school-going age. In other words, above fourteen million boys had not been brought into the primary schools. Nevertheless, the increase in this respect above 1902 was marked, amounting to 621,539, pupils, or an average annual increase of 124,307.

**Primary Education** — Formerly reading, writing, and elementary arithmetic were the limit of attainments for pupils in the vernacular schools. At present the following additional subjects are compulsory in the number of provinces indicated in each case by parenthesis: Kindergarten methods for infant classes (4), drawing (4); object lessons (5), geography (7); history as a separate subject (3), singing and recitations (2); hygiene (4); agriculture, either alone or included with object lessons (7), additional science subjects (2); mensuration (4), physical exercises (7). The following are optional in several provinces, but nowhere compulsory. English, Persian, and manual work for pupils above the infant classes.

This increased scope has been accompanied by special adjustments of the programs to the different demands of urban and rural life and by endeavors to excite the interest of pupils and parents in what are termed "middle vernacular schools." These schools, which in some provinces are classed with the secondary schools, are the crown of the vernacular system, upon them depends the welfare of the lower schools, since they supply to the latter the best qualified teachers. The enrollment in the middle schools increased from 158,706 in 1902 to 184,132 in 1907, or 16 per cent. Their normal growth,

however, is prevented by the fact that parents who are willing to keep their boys in school to the age of fifteen or sixteen years prefer an Anglo-vernacular school, since in most forms of clerical employment even a smattering of English has value. Unfortunately teaching pays less than the lower forms of clerical work, and this condition cannot be changed without an enormous expenditure. For the five years 1902 to 1907, the expenditure for primary education increased from 10,545,000 Rs (\$3,395,490) to 13,671,000 Rs (\$4,402,062), or from \$1.05 to \$1.11 per capita of enrollment. But this enrollment, as already shown, is a very small proportion of the total population of school age.

*Teachers of Primary, or Vernacular Schools* — The official reports of education in India, as a rule, give very meager data with respect to the teachers employed in the primary schools. There is a traditional respect for the office which gives the teacher some advantage, but the changing standards of social values threaten to undermine this influence, and the pecuniary considerations are assuming more and more importance. Hence the slight increase in the pay of teachers is noted as the chief element of recent improvement in the conditions of the service. Provision for training teachers is also increasing, and there has been marked advance in the standards and methods of preparation for the work, so far at least as these are set forth in official regulations. Madras, the only province that has recently reported the item, had, in 1907, a force of 30,000 teachers in the 21,379 primary schools for boys, enrolling 692,409 pupils. This is at the rate of one teacher for twenty-three pupils. In 1902 it was found that the average throughout India was one teacher to every twenty-six pupils.

During the quinquennium, salaries have been improved in the schools of Madras under public management, and a system of grading has been adopted which offers prospects of promotion in schools employing more than two teachers. In small schools, where the grading cannot be applied, the trained teachers receive about two rupees a month more than the untrained teachers. Under this system the minimum pay is eight rupees a month, from this amount it rises by successive increments to forty rupees or from \$2.59 to \$13. In eastern Bengal and Assam the salaries range from three to ten rupees a month.

*Teachers of Secondary Schools* — In respect to their financial status and qualifications, teachers of secondary schools differ radically from those employed in the vernacular or primary schools. As a rule, they are graduates of the colleges, and so far as possible the scholastic education is supplemented by professional training.

*Training Colleges and Schools* — The total number of training institutions for men teachers reported in 1907 was 318, with an enrollment of

8225 students. In these totals are included six training colleges for masters of secondary schools, with an enrollment of 270 students. For women teachers there were sixty-three training schools, with 1297 students. The total expenditure for these institutions in 1907 was 1,141,045 Rs (\$369,698).

*The Mohammedan Problem* — A favorable change in the attitude of the Mohammedans is indicated by the recent active cooperation on the part of many of their leaders in the provincial educational conferences, it may be inferred also from the fact that whereas in 1902 Mohammedans, who constitute 22.2 per cent of the population, furnished only 18.8 per cent of all pupils, in 1907 their proportion had risen to 19.5 per cent.

*Education of Girls* — Particular interest attaches also to the increase in the number of girls brought into the schools and to the endeavors to adapt the instruction to their aptitudes and social relations. The advance in this respect is due in great measure to the aroused interest of high-class natives in the promotion of the cause. A signal indication of this interest was the organization of a Social Reform conference in 1888 to consider means of ameliorating the condition of women in India. The conference, which was attended by 6000 persons, mostly Hindus, was held at Bombay at the same time as the notable assembly of the Indian National Congress. At the meeting referred to, the latter, which has become an organ for the expression of national aspirations, numbered 1889 representatives from every province of India. They gave strong support to the Reform Conference, and spread the spirit of its purposes throughout India.

This movement reaches to the very root of the social life of the nation, and marks the breaking up of the most stubborn of its traditional customs. Statistics as yet furnish no real measure of its importance, they are, rather, valuable as a point of departure for estimating its future progress. The total number of girls in all classes of public institutions in 1907, *i.e.* 579,648, was an increase of 186,480 above the total for 1902. They were distributed as follows: 273 in colleges; 61,237 in secondary schools, 513,248 in primary schools, 1267 in training schools for teachers, and the remainder in other special schools. It is interesting to note that about forty-two per cent of the girls under instruction were attending schools for boys. The total enrollment was equivalent to 3.2 per cent of the girls of school age, as against 22.7 per cent, the corresponding ratio for boys.

*Secondary Schools* — The courses of study in secondary schools are determined by the matriculation examinations of the universities. In several of the provinces measures have been taken to organize special courses in the secondary schools with a view to preparing young men for entrance upon business careers, but this movement has made little progress as

## INDIA

## INDIA

vet, and fully 95 per cent of the boys who pass through the secondary schools pursue the course leading to the matriculation examination. It follows that secondary schools and universities, including the arts colleges and professional colleges affiliated to the latter, in

which students pursue their studies after matriculation, represent a continuous course of liberal and professional education. The secondary or preliminary course of study to the matriculation examination is represented in the following scheme —

COURSE IN SECONDARY SCHOOLS AS INDICATED BY THE REQUIREMENTS FOR MATRICULATION AT THE UNIVERSITIES AGE FOR MATRICULATION 16 (MADRAS AND PUNJAB, 15)

SUBJECTS <sup>1</sup>	REQUIREMENTS BY THE UNIVERSITIES				
	Calcutta	Madras	Bombay	Allahabad	Punjab

Science . . . . .	Elective	Compulsory	Compulsory	Elective	Elective

<sup>1</sup> The complete course is arranged for 10 years in the provinces of Madras, United Provinces, Burma, and Assam, for 11 years, Bombay, Bengal, and Central Provinces, for 9 years, in the Punjab

NOTE — Physiology and hygiene are elective at Punjab, agriculture and surveying elective at Allahabad, drawing at Allahabad and Punjab

*English in the Secondary Schools, Colleges, and Universities* — While the efforts to develop vernacular schools have not been fruitless, the teaching of English still remains the pivotal point of the government system of education. The stress of effort in the secondary schools is on this language. For example, of the total of 713,342 pupils (658,305 boys, 55,037 girls) enrolled in secondary schools, 423,317 (395,513 boys, 27,804 girls) were studying English, as against 164,031 taking a classical language and 611,391 (570,456 boys, 140,935 girls) a vernacular. Pupils who enter a higher institution pass the matriculation examination in which English is an invariable requirement. When the student has matriculated and entered college, his studies are pursued entirely in the English language, whether he chooses the arts or the science course. The only exception is the special course in oriental studies offered in the Punjab University. But of students in secondary schools, only a small number, about 11,000,

annually pass the matriculation examination, and still fewer push on for a university degree. The desire for English is evidently the sign not so much of a passion for modern learning, as of the stronger passion for an immediate means of livelihood and a passport to the favor of the rulers.

**Higher Education** — The number of advanced degrees conferred by the five universities in 1907 was 837. In this number Bachelor of Laws is represented by 638 diplomas, and Master of Arts by 195.

*Movements in Higher Education* — Among the important movements in India is that which is furnishing new motives to student life. These are supplied not only by the reorganization of the universities, including the expansion of their medical and engineering courses, but also by the development of agricultural education. The first step in this direction was taken in 1901 by the appointment of an Inspector-General of Agriculture aided by a nucleus

Northwest Frontier Province	22	270	499

staff of agricultural experts. A further impulse was given to the work in 1903 by the donation of \$150,000 by an American gentleman, Mr Henry Phipps, the greater part of which sum was devoted to the establishment of the Imperial Agricultural College and Central Research Institute at Pusa in Berar. In 1905 the government of India announced the intention of setting aside twenty lakhs of rupees (\$644,000) annually for the development of agricultural experiment, research, demonstration, and instruction in India. Local governments and administrations were consulted as to the lines along which this development should be guided, and in an important dispatch, addressed to His Majesty's Secretary of State for India, the government of India defined its general policy.

The proposed scheme included the establishment in each important province of an agricultural college and research station, adequately equipped with laboratories and classrooms, and possessing a farm of suitable size, the institutions to be conducted on the same general plan as that of the central college at Pusa. Progress has already been made in the practical application of the scheme. The staff at Pusa has been recently increased by the appointment of a cotton specialist, and in the chief provinces a whole-time Director of Agriculture has been appointed, with a staff of assistants, consisting usually of the principal of the agricultural college, an agricultural chemist, an economic botanist, and one or two all-around agricultural experts. Nearly sixty experimental farms, in addition to the demonstration plots, have been established in various parts of the country.

Relations have also been established between the Education and Agricultural departments for the control of rural education, and arrangements have already been made in some of the provinces for training village schoolmasters, for short terms, either at an agricultural col-

## INDIA

lege or at the ordinary training college if the latter has a farm attached. A system of forestry schools (*q v*) in affiliation with the central school at Dehra Dun is also in course of development.

The educational conference called by Lord Curzon at Simla in 1901 laid great stress upon technical education, and as an immediate result a system of state technical scholarships was instituted. The recipients are sent abroad to pursue definite courses of instruction in subjects connected with industrial science or research. During the quinquennium fifteen scholarships were awarded, and they are now granted at the rate of ten annually.

There are at present in India no technical institutions of the highest order, but this want will be supplied by the Indian Institute of Science, to be located at Bangalore, Mysore. The project owes its inception to the liberality of the late Mr J N Tata and his family, who have donated for the purpose property in Bombay estimated to yield an annual income of Rs 125,000 (about \$40,000) a year. The Mysore government and the central government have contributed liberally to the initial expenditure and permanent support of the Institute. It is intended primarily to be a center of post-graduate study and research, particularly in science, and conducted with a view to the application of science to Indian arts and industries. The constitution of the Institute will resemble that of a university which takes entire responsibility both of teaching and examination. Its diplomas will be restricted to its own students.

The material benefits of the English system of education are most strikingly shown in the awakened interest in the practical applications of science. To understand the spiritual change that is going on under the influence of new ideals it is necessary to study the Indian press, to follow the proceedings of the educational conferences, of the National Indian Association, of the Indian National Congress, and the scientific movements initiated and financed by native citizens. The new vernacular literature shows what British education has done for the preservation of the native tongues, and reveals the spirit of Western ideas and sentiments in a Hindu form. In like manner the new religious organizations, the Brahma Samaj and the Arya Samaj, embody religious conceptions borrowed largely from the West.

Notwithstanding frequent outbursts of wild or menacing passions on the part of native leaders, their social and political activities offer irresistible proofs of steady advance toward "a higher state of society and a nobler ideal of domestic and individual life." The movement thus summed up by Sir W. W. Hunter, one of the most eminent leaders England has furnished to this transforming Empire, has its root in the schools modeled after

**English types** Its final stage is foreshadowed in the recent admission of Hindus to the government Council

**Cost of Public Education** — The total expenditure in 1907 was 559 lakhs of rupees (\$17,999,200), as compared with 401 lakhs (\$12,912,200) in the year 1902, an increase of 39.4 per cent in five years. Omitting cost of administration, and other items pertaining to the system as a whole, the direct expenditure on public education was 45,579,102 rupees (\$14,512,071), which was applied as follows for university education, including arts colleges and professional colleges, 10.4 per cent, secondary schools, 33.1 per cent; primary schools, 34.1 per cent, special schools, 7.7 per cent, for buildings and equipment, 14.7. The proportion of the total expenditure borne by each contributing source, as already defined, was as follows: by provincial revenues (including government appropriations) 33 per cent, by local funds, 16.4 per cent, municipal funds, 3.6 per cent, fees, 26.5 per cent, all other private sources, 17.5 per cent; additional public sources, 3 per cent.

The realization of the vital importance of education to the uplift of India was emphasized by the central government in 1902 by an assignment of 40 lakhs (\$1,288,000) annually for this purpose. The greater part of this fund has been devoted to primary education. In 1905 the government made a definite assignment of 35 lakhs (\$1,127,000) annually for primary education. At the same time 5 lakhs (\$161,000) were assigned annually for universities and colleges, 2½ lakhs (\$80,500) for European education, and 2½ lakhs (\$80,500) for certain new departures in technical education. In addition, an appropriation of 20 lakhs (\$644,000) is made annually to the agricultural department, a large part of which is devoted to the improvement of agricultural colleges. The local governments have supplemented these assignments by further provision from their own resources, so that the expenditure on education from public funds in the year 1907 was 296 lakhs (\$9,531,200), as compared with 177 lakhs (\$5,699,400) in the year 1902, an increase of 67 per cent in the five years.

No detailed report of this vast system operating in nine great provinces, comprising a population three times as great as that of the United States, has been issued since the fifth quinquennial report, already cited, which brings the record to 1907. Official summaries for 1908 which have been given in a foregoing table show an increase of 20 per cent in the total number of pupils in public institutions above the total for 1907. It is worthy of note that while there was very slight increase in the registration in colleges of arts and professional schools, the increase in special schools, which include normal schools and technical institutions, was very nearly 50 per cent.

The total expenditure for public education, which was equivalent to \$18,000,000 in 1907, reached \$20,000,000 the following year.

**INDIAN NUMERALS** — See NOTATION.

**INDIAN TERRITORY.** — Originally a separate territory, set apart largely for the homes of several of the civilized Indian tribes, but now included in the State of Oklahoma. Its area was 31,000 square miles, and its density of population in 1900 was 12.6 persons to the square mile. Of the total population in 1900, 77.2 per cent were white, 9.4 per cent were negroes, and 13.4 per cent were Indians.

See OKLAHOMA, STATE OF

E P C

**INDIANA, STATE OF** — Indiana was organized as a separate territory in 1800, and was admitted to the Union as the nineteenth state in 1816. It is located in the North Central Division, and has a land area of 35,910 square miles. In size it is about three-fourths as large as Pennsylvania, and four and one-half times as large as Massachusetts. For administrative purposes, it is divided into ninety-two counties, and these are in turn divided into townships. Cities and incorporated towns are usually segregated parts of a township. In 1910 Indiana had a population of 2,700,876 and a density of population of 75.2 people to the square mile.

**Educational History** — The first school in the territory of which there is any record was taught by a French missionary at Vincennes in 1793, and the second school was opened at Charleston in 1803. The first act of an educational nature was passed by the first territorial legislature, meeting at Vincennes, in 1806. This established the Vincennes University, and gave to the new institution the seminary township granted by act of Congress in 1804 for the benefit of an institution of higher learning in the territory. This institution was opened in 1810, maintained a feeble existence for a time, and in 1824 was declared extinct and its lands forfeited for the benefit of the new Indiana Seminary, afterwards University, at Bloomington.

The constitution adopted in 1816 was particularly noteworthy in that it was the first to throw careful safeguards around the various lands given by Congress to the state for education, and in that it laid a mandate on the legislature, "as soon as circumstances will permit, to provide by law for a general system of education, ascending in regular gradation from township schools to a State University, wherein tuition shall be gratis and equally open to all." In 1816 the first school law was adopted. It merely provided for the appointment of a superintendent of the school section in each congressional township, who was to attend to the leasing of the land, and that, on petition of twenty householders in any congressional township, an election should be held to elect

three trustees for the township, who were to open schools and to encourage education. As no means of securing school revenue were provided, however, the law remained a dead letter. In 1818 the Governor was instructed to appoint a seminary trustee for each county, who was to accumulate and invest funds with a view to providing a county seminary for each county. In 1824 another law was enacted, which made the system consist of rural schools, the county seminary, and the state seminary, definitely provided for the election of three trustees in each township, and made the beginnings of the district system by giving the trustees power to subdivide the township, locate school districts, appoint district trustees, erect schoolhouses by the manual labor of able-bodied residents, and examine teachers for the schools of the township. This is the first general school law for the state. Again no funds were provided, so that any schools that were opened were supported by the rate bill and by private subscriptions.

In 1833 the district system was definitely substituted for the township system. Each district was to elect three district trustees for one-year terms, who should examine the teachers and manage the school. Each district could determine whether or not it would have a school, and no one was liable for school taxes unless he sent children to school. Religious and private schools were to share equally in the school revenue. By the laws of 1836 and 1837, householders might make contracts with teachers to teach their children, under certain conditions. In 1841 the culmination of the process of decentralization was reached by the enactment of a law which made the requirement of a teacher's certificate optional with the district trustees. In 1831 the beginnings of county supervision were made in a law which provided for the election of a school commissioner for each county, for a three-year term, whose duty it was to look after the funds of the local school corporations. In 1837 the beginnings of a county system for the examination of teachers was made by a law authorizing the circuit courts to appoint annually three examiners for each county, but district trustees were still allowed to give such further examinations as they saw fit. In 1843 the first state supervision was instituted by the designation of the State Treasurer to act *ex officio* as Superintendent of Common Schools, though the duties assigned to him were almost entirely financial. In 1841 all the property of the district was made liable for a district tax to build a schoolhouse, and the year 1849 marked the partial establishment of the principle of general taxation for schools. At the fall election of 1848 a popular vote of the state was taken on the question "Are you in favor of free schools?" the result being 78,523 for and 61,887 against. As an outcome of this vote, an optional law was enacted which provided for

a general tax of ten cents on all property, and a poll tax of twenty-five cents, this to remain in the counties where paid, and further permission was granted to levy a local tax for school buildings, furnishings, and tuition. The law was not to go into effect in any county until accepted by an affirmative vote of the people, which was finally done in 61 per cent of the counties. In counties accepting the law, the office of county school commissioner, established in 1831, was abolished, and his duties transferred to the auditor, the number of district trustees was reduced from three to one to the district; and a detailed system of reports and blanks was provided with a view to securing better administration. This law marks the beginnings of a change from the policy of decentralization which began in 1824 and reached its culmination in 1841.

Very little educational progress had been made under the old constitution, and the proposal to hold a convention to frame a new constitution was seized upon as an opportunity by the friends of education. The new constitution of 1851 made it the duty of the legislature "to provide by law for a general and uniform system of schools, wherein tuition shall be without charge, and equally open to all", enumerated the items that were to constitute the common school fund, and declared it to be a perpetual fund; forbade special and local legislation with reference to schools and school funds, and provided for the election of a State Superintendent of Public Instruction by popular election for two-year terms. The constitutional provisions with reference to education have remained unchanged since then.

The school law of 1852 contained the substance of the present system. A state school tax of ten cents, to be distributed on census, and local building and tuition taxes were provided for, and township libraries established. In addition to the office of State Superintendent of Public Instruction, a State Board of Education was created, a body which has done more than anything else to establish the present well organized system of the state. At first it was made up of state officials, but in 1865 it was changed to an *ex officio* body of school men. The development of the schools was somewhat retarded by a decision of the Supreme Court in 1854 that all local taxes for support were unconstitutional, and from then until 1867, when practically the same law was reenacted and later held to be constitutional, no local taxes could be levied to prolong the term or to provide better facilities. In 1854 the State Teachers' Association was organized, in 1859 the number of township trustees was reduced from three to one, in 1861 county examiners were given larger power in regulating the issuance of licenses to teach; in 1865 county teachers' institutes were begun, in the same year the State Superintendent gave up the power to grant local licenses, and the State

Board began to issue state certificates; in 1865 the state normal school was established, and opened in 1870; in 1872 the first township high school was started; in 1873 the office of county superintendent was created out of the office of county examiner, provision was made for the organization of separate city school systems with power to employ a city superintendent, and the State Board of Education began to commission high schools, in 1889 kindergarten and night schools were authorized, and the State Board of Education was created a State Textbook Commission to select a uniform series of textbooks for the schools of the state; in 1894 a state course of study was issued; in 1897 the first compulsory education law was passed, in 1899 the county superintendent's term of office was extended to four years and educational qualifications were established for the office, the use of uniform examination questions furnished by the State Board of Education was made mandatory, and definite recognition of high schools was made in the state law, in 1901 the time of attendance required by the compulsory attendance law was changed from twelve weeks to the entire school session, and in 1907 a minimum wage law was enacted and the State Board of Education was created a State Training School Board, with power to designate institutions as training schools, and with a view to requiring all teachers in the state to secure some kind of professional training. In 1911 an optional medical inspection law was passed, county superintendents were given a fixed salary instead of a *per diem*, and a state agricultural and industrial commission was created. Along with all these changes has come a great change in the attitude of the people of the state toward public education, which has done much to make educational progress possible.

**Present School System** — At the head of the school system is a State Board of Education and a State Superintendent of Public Instruction. The State Board is composed of the Governor, the Superintendent of Public Instruction, the presidents of the state university, Purdue University, and the state normal school, the city superintendents of the three largest cities, and three citizens of prominence engaged in educational work and appointed by the Governor, one of whom must be a county superintendent. The Superintendent of Public Instruction is president of the board and acts, in part, as its executive officer. This board has gradually, by careful and intelligent work, secured large authority for itself and has done very valuable work in fostering new and desirable educational undertakings. The board is charged with the duty of considering practical school questions, of examining teachers for state certificates; of preparing examination questions to be used by all county superintendents in the examinations for county certificates; and of examining and commission-

ing high schools. The board also acts *ex officio* as a State Board of Textbook Commissioners, to adopt uniform textbooks for the schools of the state, fix their sale price, and make contracts with publishers, and as a State Training School Board, to accredit institutions to train teachers for the various kinds of schools of the state, to prescribe courses of study, etc.

To the State Superintendent of Public Instruction is given the general supervision of the schools of the state and the care of the school funds, he must visit each county once in two years and examine the auditor's books and ascertain the condition of the school funds, prepare blanks and forms and prescribe methods of bookkeeping, apportion the school funds semi-annually to the counties; decide appeals from the county superintendents, and make a biennial report to the legislature and an annual report to the Governor. He also serves *ex officio* as a member of the Board of Trustees of the State Normal School.

In each county there is a county superintendent of schools, elected for four-year terms, by the township trustees. He must hold at least a three years' teachers' license to be eligible. He conducts eight public examinations each year for county teachers' licenses, using questions furnished him by the State Board of Education, decides appeals from the decisions of township trustees, provides for the examination of all graduates from eighth grade and from the town and township high schools of the county; conducts an annual teachers' institute, holds a preliminary institute of the teachers of each township before the opening of schools, and visits each township institute once each year, visits schools, carries out the instructions of the State Board and the State Superintendent, inspects the county books to see that the school funds are properly preserved, and makes an annual report to the State Superintendent and to the State Bureau of Statistics. A county board of education, consisting of the county superintendent, township trustees, and the chairmen of the town and city boards of education of the county, meets semi-annually with the county superintendent to consider the general wants and needs of the schools, and all matters relating to the purchase of school supplies.

Each county is divided into townships, cities, and towns. For each township one township trustee is elected by popular election. He has charge of the roads, bridges, poor relief, and schools of the township. He has general charge of the educational affairs of the township; power to locate and establish a sufficient number of schools; may establish a township high school if he has twenty-five grammar school graduates in the township, or may unite with other township trustees for the purpose; must maintain a six months term and shall authorize a sufficient tax for the pur-

pose, within the limits set by law, may abandon schools and transport pupils with the consent of a majority of the residents of the school district, must take an annual school census, may transfer children and their funds to other townships, employs teachers and makes contracts with them in writing, according to the minimum wage law, and must make a detailed annual report to the county superintendent and the board of county commissioners.

Cities and incorporated towns are governed by separate and distinct school officials, though otherwise operating under the general school law, unless of over 50,000 inhabitants, in which case they may have special laws relating to the form of government. The city council, or board of town trustees, appoints three school trustees, one each year for three-year terms, to manage the schools. They have the same duties and powers as township trustees, and, in addition, may establish night schools in a city of over 3000 inhabitants, kindergartens in one over 6000, and a system of industrial training in one over 50,000. Cities of 100,000 or over are governed by a board of five school commissioners, nominated by petition and elected by the people, and to them are given certain large powers.

For each subdistrict in the township, the school director is elected by the parents each year, or appointed by the trustee if the parents fail to elect. The meeting of parents may also add additional branches of study to the course of instruction of the school, designate the time of year at which they desire the school to be taught, direct that repairs be made, and petition the township trustees to move, sell, or repair the schoolhouse, or to dismiss the teacher. The school director presides at all district meetings, serves as a means of communication between parents and township trustees; repairs the schoolhouse and provides fuel and supplies, and suspends or expels pupils.

The State Board of Education, acting as a State Textbook Commission, adopts a uniform series of textbooks for the elementary schools of the state for ten-year periods, copybooks, histories, and geographies excepted, these being adopted for five-year periods. A depository is designated in each county, and from this books are sent out to dealers and trustees throughout the county for sale. All schools in each township, cities and incorporated towns excepted, must be taught an equal length of time. The Bible is not to be excluded from the public schools of the state. Colored children may be taught with other children, or in separate schools, as communities may prefer.

**School Support** — The state originally received 650,317 acres of land from the sixteenth section grant, but most of this was sold when the state was very poor, and brought but little. The total grant has produced a little less than

two and a half millions of dollars. The state also received \$860,254.44 from the Surplus Revenue of 1837, one half of which was added to the permanent school fund. From swamp lands, saline lands, bank taxes, fines, forfeitures, and escheats, additional amounts have been added, so that the total permanent fund at present amounts to about eleven millions. The interest on the Congressional Township Fund is distributed to the townships to which the fund belongs, but the interest on the remaining school fund, together with 94.8 per cent of the state school tax of 13.6 cents, is distributed to the different counties of the state, and from the counties to the townships, towns, and cities, on the basis of the number of children reported between the ages of six to twenty-one. The remaining 5.2 per cent of the state tax is held as a reserve fund, to aid poor and deserving districts to enable them to bring their school term up to the minimum required by law. All state money must be used for teachers' salaries only. No county school tax is levied, but the surplus dog fund and license fees go to the school fund of the county. Trustees in townships, towns, and cities up to 100,000 inhabitants, may levy additional local taxes up to fifty cents on the \$100 and a poll tax of fifty cents for extending the school term (tuition fund), and a similar tax but with \$1 poll for buildings, supplies, and other expenses, including salaries. Cities of over 100,000 inhabitants may levy up to fifty-seven cents for all purposes. About two thirds of the total revenue comes from local sources.

**Educational Conditions** — The state, generally speaking, has relatively good educational conditions. There is but a small percentage of foreign born in the state (5.8 per cent), and these are largely settled in a few districts, and in the wealthier part of the state. There are but few negroes (2.3 per cent), and these are mostly in cities, which renders the problem of the education of the colored race easy to handle. Agriculture and manufacturing are the chief resources. Of the total population about 65 per cent live in country districts. The southern third of the state is much poorer than the central and northern portions, and has much greater difficulty in maintaining its schools.

The compulsory education law, which requires that all children, seven to fourteen years of age, must attend school during the time the schools are in session, is well enforced in the cities, and fairly well enforced elsewhere. The county board of education in each county is constituted a board of truancy for the county, instructed to appoint one truant officer, and charged with the enforcement of the law. Cities of 5000 constitute separate truancy districts, and all cities may appoint truant officers to enforce the law. If children are too poor to attend school, the township trustee or the city board of education must provide books and clothing. Homes for incorrigibles

and confirmed truants may be established and a special tax levied for their maintenance.

The average value of the schoolhouses of the state was about \$3300 at last report. This has advanced rapidly within recent years, owing to the abandonment of many poor and small buildings and the substitution of one well-built central consolidated school in their stead. The movement for the consolidation of schools and the transportation of pupils to a centrally located school has made very rapid headway in Indiana, some of the best consolidated schools in the country being found in that state.

Practically all schools outside of cities follow a uniform state course of study, which is issued by the State Superintendent, along with a series of directions and bi-monthly questions on the work to be covered. The required monthly township institute also tends to unify the work of the schools. The schools are well graded, and high schools are numerous. Manual training is taught in nearly all of the cities and in many of the town and rural consolidated schools. Instruction in domestic science is also given in many places. There are many public libraries in the state, a Public Library Commission has charge of the public libraries provided by the state, and liberal township and city taxes for library purposes are allowed. Each community may do as it desires with reference to providing separate schools for the colored race, but equal educational facilities must be provided. While sectarian or denominational instruction is not allowed, the law provides that "the Bible shall not be excluded from the public schools." Private and parochial schools are required to report statistics to the county and state school officials. These schools exist chiefly in the cities, and enroll but about 3.5 per cent of the total enrollment of the state.

**Teachers and Training** — The yearly salaries paid have increased 50 per cent in ten years, being now, on an average for all teachers, about \$500. This is due in part to the minimum wage law, which now requires trustees to sign written contracts with teachers, with a \$100 fine if the contract is made at a lower rate than the minimum wage allowed by law. No statistics are available from which the percentage of teachers in the state who have had normal training can be determined. The minimum wage law of 1907 provides that all new teachers must have had a high school education or its equivalent, and have had in addition twelve weeks in a professional training school for teachers in the case of all beginners, twenty-four weeks in the case of those paid on the basis of three cents, and must be graduates of a professional school to receive salary on the basis of three and one half cents. (The basal minimum is multiplied by the grade made in the examination for the respective licenses to give the daily wage.) The State Board of

Education is designated as a State Training School Board, to define standards and equivalents, designate institutions in which the professional work may be done, and to outline professional courses of instruction. In addition to these designated institutions, the state maintains a large state normal school at Terre Haute.

For the improvement of those in service, besides the monthly township and the annual county institutes, there is the Indiana Teachers' Reading Circle, organized in 1883, which is one of the most successful organizations of its kind in the United States. Though conducted by the State Teachers' Association, its work has been accepted by the State Board of Education, and forms a part of the examination questions for teachers' licenses. About 85 per cent of the teachers of the state are members of the organization. The Young People's Reading Circle, a branch for children, was organized in 1887.

**Secondary and Higher Education.**—The high school has had a large development in Indiana, there being 730 high schools in 1910 with 2054 teachers employed. Of these 519 were township high schools and 355 were fully accredited four-year high schools. This development is due in large part to the wise policy of the

State Board of Education, which fostered and aided the movement years before the high school was incorporated into the state school system. A commissioned high school must have a certain equipment and a four-year course of study, at least two teachers, and at least an eight months term, and the graduates of such schools are accepted into the different state and private institutions of higher learning without examinations. Some of the noncommissioned high schools lack only in length of term, while others are two and three-year schools in process of evolution. Seven cities maintain high schools for the colored race, and four cities maintain manual training high schools. The money for the support of high schools comes from the same sources as that for common schools.

At the head of the school system of the state is the State University of Indiana (*qv*) at Bloomington, opened in 1824. Purdue University (*qv*) at La Fayette, opened in 1874, which owes its origin to the Land Grants of 1862, is a second higher institution, supported by the state. There is also a number of old denominational colleges in the state which share with the state institutions the work of higher education, and a number of private normal schools which offer academic and normal work.

Besides the two state institutions, the state maintains the Indiana State School for the Deaf at Indianapolis, founded in 1843, the seventh of its kind in the United States, the Indiana State School for the Blind at Indianapolis, founded in 1846; the Indiana School for Feeble-minded Youth at Fort Wayne, founded in 1887; the Indiana Soldiers' and Sailors' Orphans Home at Knightstown, founded in 1867; the Indiana Reform School for Boys at Plainfield, founded in 1867, the Indiana Industrial School for Girls at Indianapolis, founded in 1869; and the Indiana Reformatory, established in 1906, an institution for neglected and wayward children, and an outgrowth of the compulsory education law.

**INDIANA STATE UNIVERSITY, BLOOMINGTON, IND.**—The first constitution of the state, adopted in 1816, made provisions for a state university as a part of the public educational system. In 1820 a state seminary, later called Indiana College, was founded. By act of the General Assembly, 1838, Indiana College was raised to the rank of a university, and in 1852 was officially recognized as the state university. In 1856 as the result of a lawsuit the university was deprived of a part of its lands, and the loss was made up by a new grant from the federal government, which secured the future development. After a brief setback during the Civil War, progress continued. The Federal Land Grant of 1862 created some difficulty, since the university was at the time not definitely prepared to meet the requirements of the act. A new institution was founded through a gift of Mr. Purdue, to which the federal grant was assigned. In 1867 the first state appropriation was made to the university and in that year women were admitted to the classes. The Indiana University School of Medicine was established in 1903 and gave a two years' preparatory course. In 1908 the Indiana Medical College, located at Indianapolis, was united with it under the title of the former. Under the administration of President David Starr Jordan, who entered office in 1885, the university advanced to the rank of the leading institutions. In 1889 the school of law, which had been discontinued, was revived with a three-year course. In 1895 and 1903 the revenue from the state was increased, the university receiving four elevenths of a tax of two and three fourths cents on every one hundred dollars of taxable property. In 1908 the School of Education was established. The government of the university is in the hands of a board of trustees elected partly by the State Board of Education and partly by the body of alumni since 1891. The departments of the university are the college of liberal arts, school of education, graduate school, school of law, and school of medicine. The admission requirements are sixteen units. Candidates are admitted by certificate from commissioned high schools (see HIGH SCHOOLS, ACCREDITING OF) or by examination. The college gives the following courses leading to the A.B. degree—classical, commercial, chemical, engineering, arts-law, arts-medicine, journalism, pedagogy. A summer session is also maintained. The enrollment in 1909-1910 was 2564, distributed as follows: college, 1828; graduate school, 137; school of law, 143; school of medicine, 248; school of education, 236. The faculty at Bloomington consists of seventy professors and more than a hundred junior officers of instruction.

**INDIANS, AMERICAN, NATIVE TRAINING.**—(The general discussion of the education of primitive peoples is given under that title. The present article is limited to the discussion of the concrete practices of selected American tribes by one who was educated under the conditions he here describes.) It is generally assumed that the American Indian had no definite standards of his own, by which to measure life and initiate the young into the tasks and philosophy of the race. This is not true. His ideals were surprisingly high, and he found it impossible to accept the material gains of a "superior race" without spiritual loss. For them he has sacrificed against his will the simplicity and the generosity of his manhood.

Nature gave to our mothers strength of body, and that sure intuition which led them to absorb and to transmit to the unborn all that is most vital and profound in the breathing universe. Silence and solitude in the surroundings of the young wife—the expectant mother, a hush that was only broken by the sighing of the pine wood or the thrilling orchestra of the distant waterfall—these were the foundation of our spiritual training. Again in solitude and silence we learned to rise to that which is beyond ourselves—the mysterious and holy! In due time the child is born, and becomes at once the center of the family. To this rude cradle the whole clan pays its respects, as the latest comer from the Mysterious, the Great Giver of all life. The mother will never allow any other duty or pleasure to interfere with her duty to her child. From the moment that its wondering eyes opened upon her in the wilderness, she has accepted a sacred trust. She straps the cradle to her back while busy with her household duties, or suspends it from the bough of a tree, where she can still see and talk to the little one, ever pointing him to nature, and beyond to nature's God. He is taught from infancy that he is brother to the animal people,—the innocent, dumb creation,—and that the trees and the rocks are the embodiments of a mysterious Power, and therefore worthy of reverence. Above all things he must seek spiritual guidance fasting and in solitude; he must honor and respect his elders, and learn to hold his peace. Words are weak, but silence is perfect equipoise, the evidence of a perfect self-control, and it is silence the Indian cultivates. He is admonished to be truthful and chaste, to love his country more than life, and never to violate the trust of a friend. There was much of the stoic in our philosophy, and of the ascetic in our ideals. The boy is early forbidden to say or think:

"This is mine!" He is taught that the love of possessions is a weakness to be despised, and that one should desire to have only in order to give. This law forever wiped out from the Indian mind all commercialism and every possibility of material progress under tribal conditions. Trained to divide his last mouthful, he could not easily compete with his brother in a brutal and selfish struggle for existence.

In order to be a perfect man, one must have a perfect, symmetrical, and efficient body. This demands absolute self-control in eating and in all the pleasures of sense. The Indian exercised constant self-denial, and accustomed himself to continual and severe exercise from the age of six to sixty. His courage was early developed so that he should fear neither pain nor death. Living the natural life, he had no false modesty; he was naked and not ashamed; his courtesy was from the heart.

When the boy is seven or eight years old, his father begins in earnest his training for manhood. He is occasionally called upon to fast for a day, and the father usually fasts with him for the sake of example and sympathy. They both blacken their faces for a sign, and the boy's comrades make the ordeal more difficult by secretly tempting him to break his fast. His nerves are tested and strengthened by awakening from sleep with a sudden war-whoop, or by sending him for water after dark in a strange country. Perhaps the father compels him to dodge around a tree trunk, while he sends arrows whizzing about his ears! His faculty for observation and reasoning is developed not alone by constant roving, but by close questioning as well. Each night he must be prepared to stand an examination on the things seen and learned in the woods that day. The language of footprints includes the distinction between the moccasin of different tribes, the age of the trail, and the probable intention of the traveler. In the case of an animal, one should tell the sex, the number of hours since he passed, and something in regard to the circumstances, as whether he was hunting or hunted. It was a common thing among us to be able to distinguish the footprints of members of one's own family, as well as to know that of any member of the clan from an outsider's. The position of the sun and stars and the ordinary weather signs and appearances must be mastered for a guide to time, direction, and locality. It is almost unheard of for an Indian to lose his way. He is carefully trained from an early age to be independent in the woods, so that he can take care of himself in an emergency. If he is belated and overtaken by darkness, he must know how to settle himself for the night without anxiety. He must be able to take fish and birds without a weapon, know where to look for edible roots, berries, and mushrooms, and how to start fire with pieces of punk or flint and knife. He is taught to make arrows for himself under the

direction of his grandfather, who is usually his very good comrade, and later the bow, with which he assiduously practices the off-hand shot. He must also learn to throw stones accurately. The art of finding and outwitting the game is a more complicated one, in which he is systematically trained by his father, grandfather, and male kinsfolk. In physical training much stress was laid upon endurance, and the disproportionate muscular development of the white athletes was not desired. Swift ness and agility were essentials. The young warrior of our people might have posed as a model for the Apollo, and his sun-browned skin was as smooth and fine as satin. The jet-black hair received painstaking care, and among the Plains Indians sometimes attained extraordinary length.

He never knew when or under what conditions he might be tried, hence he must be a "minute-man" both in war and hunting. He was a public servant—one who would be forever disgraced if he failed to respond when called upon for difficult or dangerous service, in summer or winter, by day or night. He must be always ready, able to run without food or water, if necessary, and to sleep on frozen or wet ground, for such was his Spartan training. At the same time he had much personal liberty as a boy, and was rarely punished or severely scolded. We Indians, even in childhood, had a peculiarly sensitive dignity and intense self-respect, which was cultivated by our elders by every means within their power. The well-born child was distinguished and marked out for an honorable future by a series of festivals given by the parents to celebrate and announce every stage of childish progress, such as the first step, the first shot with bow and arrow, or the ear-piercing, which was a sort of christening ceremony. This gave him, while still very young, a sense of standing and responsibility as a recognized member of the clan.

His mental discipline consisted largely in memorizing the legends of his people and the brave deeds of their heroes, whether traditional or authentic, all of which he was expected to have at his tongue's end. In this tribal lore the wise and old men were the accredited teachers. The young man generally said very little, willing to remain an apprentice until he should be admitted to the war feast or the council, which he well knew must depend entirely upon his own courage and success. He had played with his sisters and girl cousins until he was twelve years old, but if he were seen with the girls after that age, the other boys would threaten to put a dress on him! It was now time to devote himself wholly to manly occupations, and he might even go upon the warpath as early as fourteen or fifteen. The first *hambeday* (religious fast or vision), came at about the same time, and was a period of solitary communion with the *Great Mystery*.

With the ancestral philosophy as a foundation, the Indian's out-of-door life made him a strong reasoner and an independent thinker. He was as ambitious to be a successful hunter as a warrior, since the good hunter is also a feast-maker and the social center of the tribe. Many of our most noted characters were of this type, men of peace, whose generosity and good will gained for them not only the favor of their own band, but intertribal distinction.

On the other hand, his sister was put through a course of training equally rigid in its way, according to our ideas of the womanly character and vocation. We Indians held firmly to the belief that purity and modesty are the foundations of womanly strength and of the sacredness of home. All her energies were subdued to this end. Free and sportive when with her girl companions, in the presence of man she became instantly mute, averting her face from him with child-like, yet maidenly, timidity and reserve. The use of the eyes was strictly inculcated by the careful mother, and the "straight eye," that guarded, yet straightforward look, was deemed an index to the purity of the maiden. There was, in the old days, no social gallantry or meeting of the young men and maidens, save in one or two formal dances. Even in these they did not take partners, the boys dancing on one side of the ring, and the girls opposite. It was a sort of Quaker gathering. The young girl must not joke or talk freely even with her own brothers, or with any man except her two grandfathers. When one came to ask her hand, she was not expected to reply at once, but to keep him on probation until satisfied that he was sincere and worthy an answer. She had sometimes a little teepee of her own within the parental lodge, and went nowhere without the protection of her grandmother, who was considered to be her natural guardian and supported the part with much dignity. Every year, from the age of twelve or fourteen, she joined in the virgins' feast, where all take their oath upon the "sacred stone" to their purity and innocence, vowing to remain chaste until their marriage. The whole tribe attended this feast as spectators, and if any girl was discovered or suspected to be untrue to her vow, she might be publicly disgraced.

From early childhood the "little woman," as she is called, worked side by side with mother and grandmother, helping or imitating her in beaver-like industry. Tanning and dressing skins, drying meat, making and pitching the skin teepees, fetching wood and water, cooking — these were her hardest tasks, to which she added the making and mending of the family clothing and moccasins, the gathering and drying of fruit, wild rice, and roots for winter use. All these the little girl "made believe" in her earliest play, and learned to achieve gradually, as strength and skill permitted. She usually became an adept in needlework, whose

pride it was to see that her brothers' and male kinsfolk were becomingly attired; nor were the poor and old people of the clan forgotten. While hunting, fishing, and war weapons were made by the men and boys, the women made everything else, including more or less fine pottery in many tribes, the weaving of rush mats and blankets of wool, basket-making of vegetable fiber, and canoe-making. All of these are decorated in symbolical designs, conventionalized from natural objects, such as hills, a serpent, lightning, leaves, and flowers, while the marvelous combinations of color are likewise adapted from nature with much of native artistry. The Indian girl, as well as her brother, was taught to repeat sacred stories and legends of old, especially those which have a feminine character. Even her lullabies spoke of the doe, the mink, and the ermine (to which woman is often compared in the language of compliment), or of the fairy sisters who lure the lone hunter to follow their musical laughter into the depths of the forest. Her dress was that of a miniature woman, a long, straight robe reaching nearly to the ankles, with wide flowing sleeves; and her home-made dolls were attired after the same unvarying fashion. Her long, black locks were dressed with perfumed oil, smoothly plaited and sometimes adorned with beads or shells to match her necklace, but the woman might not wear eagle feathers, unless rarely in a sacred dance. She must learn by practicing when alone how to laugh musically and gracefully, must sit sidewise in modest feminine fashion — never cross-legged like a man, and etiquette even prescribed a distinctive speech, many words being used only by women or having a feminine termination. The Indian girl could run, swim, and ride almost as well as her brother, and as she had much labor to perform, the woman was often quite as muscular as the man, and of heavier build. She was apt at woodcraft, and a close observer of bird and animal life, particularly of their home-making. She knew the plants and flowers better than he, since it fell to her to gather and preserve them for food or medicine.

Such was the practice and such the precepts by which we were prepared to bear an honorable part in the life of our people.

**Present System of Education.** — It is said that one of the early councils with the natives of Virginia was concluded by an offer on the part of the colonists to educate several of the children of the forest with their own sons. The Indians retired to deliberate upon the matter, after which they replied as follows: "We thank you for your generous offer. We have decided that the education of your schools will not benefit our children in the life that is ours, but we desire to convince you of our friendship for the white man. If you will entrust us with three or four of your most promising young men, we will charge ourselves with their edu-

cation, and we will *make men of them*." The story illustrates, as well as may be, the complacent attitude of the conquering Anglo-Saxon, who has been satisfied from the beginning that his kind of education was not only best for himself but for his red brother as well, and that he was doing him the greatest favor within his power by forcing upon him the customs, philosophy, and religion of an alien race. On the other hand, it shows us the unlettered sage, firm in his original belief that his own ways were best for himself. He was not anxious to impose them upon others, but made his counter-proposal as the most courteous, and at the same time the most logical method of conveying his answer. The first American had not the least desire to copy or emulate his unbidden guest, whose vices and weaknesses provoked in him at least as much contempt as his brilliant achievements aroused wonder and admiration. This position he maintained with dignity in every instance until convinced that he was beaten, that he was no longer to be allowed to live his own life, and must learn the language, manners, and religion of his conquerors or be trampled under their feet. When this point was reached by an individual or a tribe, and not until then, he has voluntarily placed his children in school and set himself with determination to "walk the white man's road."

The evidences of his success in this difficult undertaking are so many and so varied, covering, as they do, a period of over three hundred years, that it is curious how long the popular fallacy has persisted that "the Indian cannot be civilized." The only excuse for such a view is to be found in the simple fact that the Indian did not in the main, or until he was pushed to the wall, desire to be "civilized," and in the further fact that until a very recent period no systematic or comprehensive efforts were made in that direction. Sporadic and individual efforts there have always been since the date of the very earliest settlements in America, which efforts have, from the beginning, met with enough success to prove — if proof were needed — that the natives of America are as capable of taking on an alien culture as were the wild Celts of adopting the manners and language of the conquering Saxons. Man is, after all, a progressive animal.

The earliest education of the natives of this country by its invaders may be said to have been the undesigned and inevitable alteration wrought by contact. Even without any conscious wish or intention on either side, a primitive people could not live in close touch with one more advanced, and not suffer a profound change. The Indian passed at once into the iron age. In every case, the first fruits of civilization were knives, firearms, and whisky. These tended toward destructive internecine wars, as they inflamed and brutalized his simplicity; and the next wave brought with it other dangerous and corrupting elements which

he was as little formed to resist. Venereal disease and small-pox, scrofula and tuberculosis undermined his native vigor and decimated the tribes, or in some instances exterminated them altogether. The white man literally possessed nothing which the Indian wanted or needed, while practically all the possessions of the lords of the soil were coveted by the invader. He could not exist without them, and in order to secure them he created artificial desires which he could satisfy, but at frightful cost to his victim. Trade was at the first a mere farce, since the red man had no conception of material values, no taint of commercialism. He was generous and hospitable, willing to give of his abundance without return, and to accept pretty trifles with gratitude. Told that a string of blue beads were made from a piece of the sky, the credulous chief was ready to exchange for them all that he had! But after two or three generations of schooling in the tricks of trade, he became almost as sly and avaricious as his teacher, and in the same way he has come to be in many instances a "grafter" in politics and a hypocrite in religion. This process in its several stages, differing in detail but alike in its general features, has been in evidence in widely separated portions of the continent during the past three hundred years.

Those enthusiastic propagandists and able organizers, the Roman Catholic clergy, have been leaders in the designed and deliberate instruction of the natives, not only in religion, but in art and industry. Their courage and good intentions are worthy of all praise, however one be inclined to demur as to the benefit of imposing their system in its entirety upon a naturally reverent and superstitious people. They have commonly succeeded in grafting their ceremonies upon the "pagan" ritual, and by a free use of holy water and the sign of the cross have made more nominal converts than all other religious bodies put together. It should also be admitted that they have much that is tangible to show for their labors. As early as 1567 the agricultural education of the Indians in Florida was attempted by the Jesuits, and nearly two centuries later early Franciscan missions in California and other parts of the southwest achieved results mainly practical and social. Domestic animals and the agricultural arts were permanently acquired. The discipline of the fathers was rigid, and amounted to a benevolent servitude. In 1834 the missions were secularized by the Mexican government against the protests of the order, and their extensive property divided among the Indians, who soon lost or were deprived of it. Early French missions included those among the Abenaki in Maine, the Hurons in Ontario, Michigan, and Ohio, the Iroquois in New York, the Ottawa in Wisconsin and Michigan, the Illinois in the Middle West, and the tribes of Louisiana. Bishop Laval founded

a school at Quebec for French and Indian youth. Other pioneer missionary work, extending into the nineteenth century, was conducted in the Missouri River region by Father Ravoux, Father De Smet, and other less noted explorer-priests, among Flatheads, Chippewas, and Sioux.

One of the avowed objects of colonizing Virginia, as stated in the early charters, was that of "bringing the infidels and savages to human civility!" The council of Jamestown in 1619 voted to educate Indian children in "religion, a civil course of life, and in some useful trade." A few were taken to England to be educated. In 1663 the colonists demanded children as hostages for the good behavior of the Potomucks, which hostages were to be "civilly treated and brought up in English literature." At about this time King James issued a letter authorizing collections to be taken in the cathedrals for "the education of the children of these Barbarians," and about fifteen thousand pounds was received. In 1621 the Company had allotted one thousand acres of land and received subscriptions to endow an Indian school, wherein the "most towardly Indian children" should be fitted for college. But an end was put to these early projects by a sudden uprising of the incensed natives to rid the land of the troublesome invaders; and although the larger part of the colonists owed their lives to the warnings of Christian Indians, no further efforts were made until the founding of William and Mary College in 1693. The charter of this institution declares one of its main objects to be "the propagation of the Christian faith amongst Western Indians." There was, apparently, some difficulty in obtaining pupils, one explanation of which is given by Governor Spotswood, who writes to England "They (the Indians) urged the breach of a former compact, when, instead of their children receiving the promised education, they were transported, as they say, to other countries and sold as slaves."

In Massachusetts the famous "Apostle to the Indians," John Eliot, who translated the Bible into the vernacular, labored with them in things secular as well as spiritual. He founded the Christian Indian town of Natick, laid out, built, and planted by Indian labor, and it was not his fault that the "Praying Indians" of Natick, who are said to have been thrifty and industrious as well as diligent church-goers, suffered cruelly from race prejudice during King Philip's War. Daniel Gookin was appointed Superintendent of Indians in the Massachusetts colony in 1656, and held the office until his death thirty years later. His duties included the conduct of schools among them, as well as the preservation of good order and discipline. These schools, however, were much hampered by lack of means and of suitable teachers, two diffi-

culties which have largely persisted to this day. It was a part of the New England plan, as in Virginia, to give to selected youth a college education, to fit them for the Christian ministry, and to instruct their wilder brethren. The charter of Harvard College contains a provision for the education of Indians, and not a few availed themselves of it. But the sudden change to a sedentary and indoor life caused many to fall sick and die. One youth who was about to be graduated, "a good student and pious man," says Gookin, was shipwrecked and drowned off Nantucket, and another who had taken his degree died soon after "of a consumption." A third student at twenty years of age is said to have been "an extraordinary Latin poet and a good Greek one."

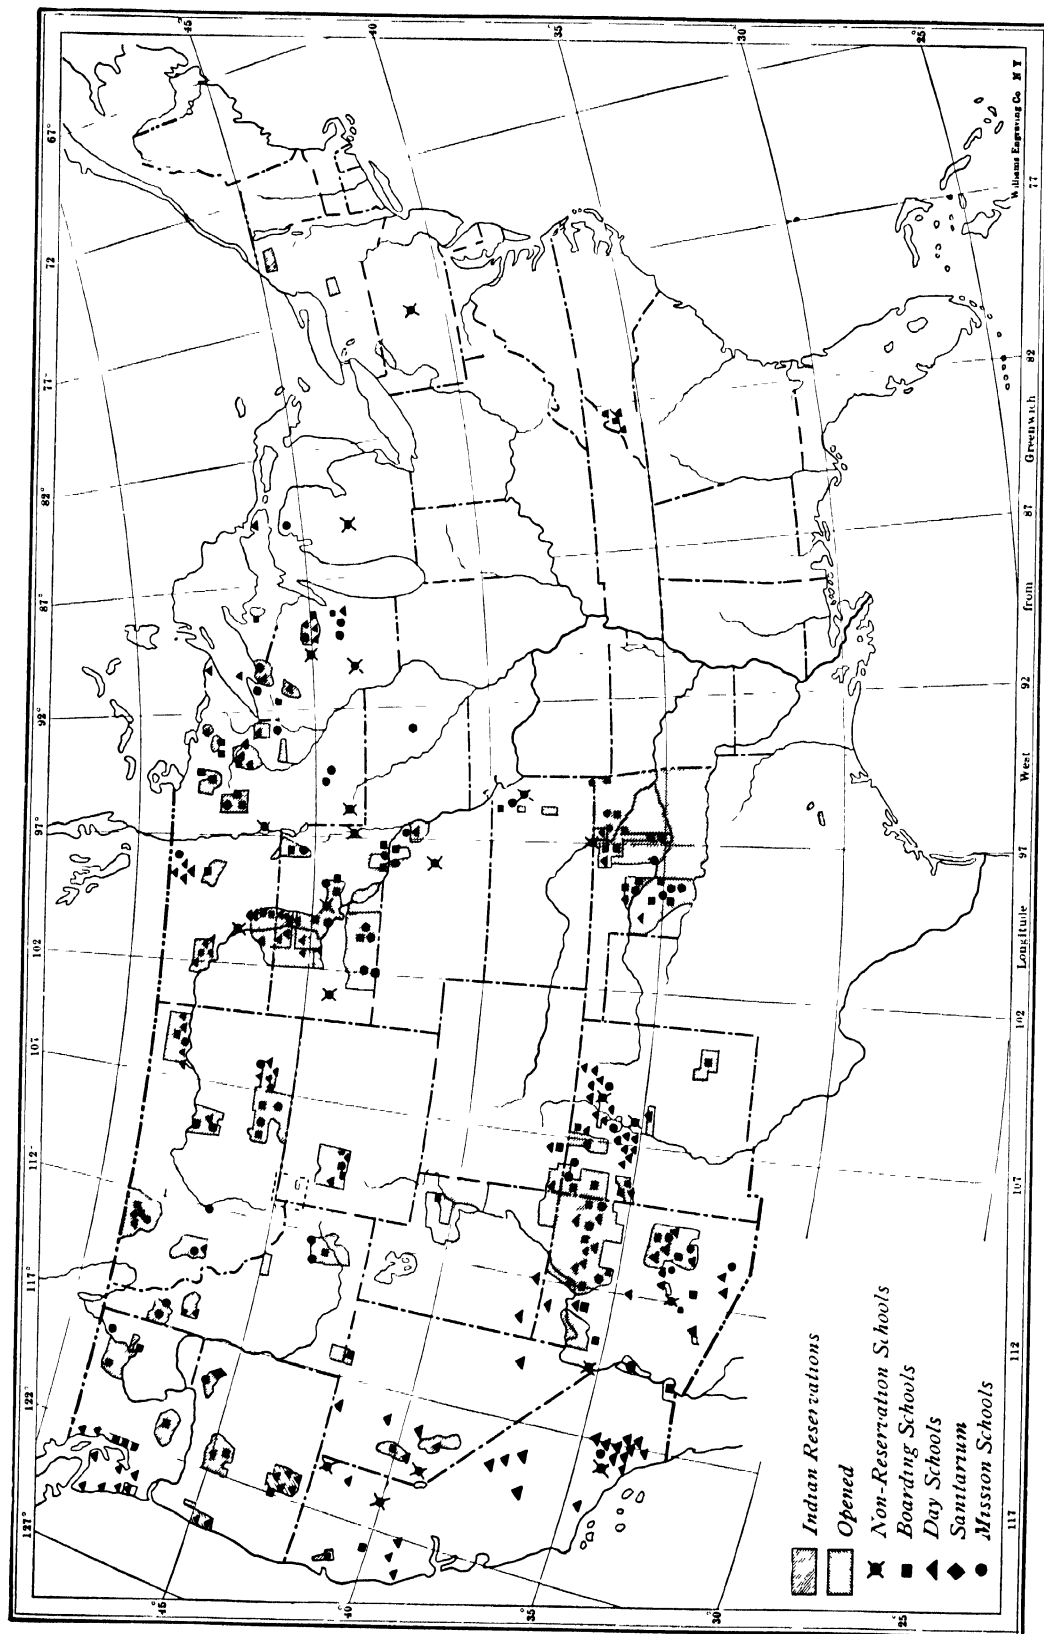

At about the middle of the eighteenth century, an industrial boarding-school was established at Stockbridge, Mass., and the missionary at that place wrote of them: "There are many Indian youth that read English well." Several of these completed their studies afterward at Dartmouth College, which was founded in 1755 as "Moor's Indian Charity School." The school originated with the Reverend Eleazar Wheelock of Lebanon, Conn., who took into his own family a Mohegan by the name of Samson Occum. The youth proved an apt pupil, and became a Christian preacher of much force and distinction. He was sent to England to raise funds for the school, after it had been incorporated as a college and removed to New Hampshire, and was highly successful in this, being a most interesting speaker. He also wrote a number of striking hymns, one of which is sung in the churches to this day. At Dartmouth, Indian and white youths were educated together, many of the latter being trained for missionary work among Indians. The gifted and friendly chief of the Six Nations, Joseph Brant, who was brother-in-law to Sir William Johnson, was one of its early scholars, and afterward sent two of his sons there.

The Moravian missions in Pennsylvania were very successful, and the story of the sad exile of the converts from their prosperous villages and the brutal massacre of ninety innocent and unresisting Christian Indians in 1781 is one of the blackest chapters in history.

There were Russian and English schools for the natives established in Alaska in the latter part of the eighteenth century. In the Canadian colonies much pioneer work was done by Roman Catholic missions, but it was not until 1867 that the provincial government took up the work systematically. In 1904 there were in Canada 24 industrial, 46 boarding, and 228 day schools in operation. The natives of the Dominion are for the most part law-abiding, prosperous, and contented, having proved neither a menace nor a burden to the commonwealth.

The first appropriation by the United States government for Indian education was the sum of

INDIAN EDUCATIONAL INSTITUTIONS.

five hundred dollars voted to Dartmouth College in 1775. Cornplanter, speaking for the Senecas, appealed to General Washington in 1776 for a teacher, "to teach our children to read and write and our women to spin and weave," and agreed to send nine Seneca boys "to be under your care, and learn to become wise and good men." The first general appropriation of \$10,000 was made in 1819, and until 1870 all government aid for this purpose passed through the hands of missionaries of various denominations. Afterward, for nearly thirty years, government schools and church schools aided by government funds existed side by side, until in 1900 these "contract schools" were abolished, the religious societies assumed the care and support of their own schools, and the annual Congressional appropriation is applied under the law entirely to schools conducted by the government. The original \$10,000 had gradually increased by 1870 to over \$100,000, but it should be remembered that this appropriation, which has now grown to several millions annually, is in large part the Indians' own money, being interest on trust funds or made in fulfillment of treaty stipulations, "for value received." It is not disbursed as charity, but as partial payment on an enormous debt. By this time, also, there were constant appeals and demands from the Indians for the establishment of new schools, and the further development of those already in existence.

In 1878 seventeen prisoners of war from St. Augustine, Fla., were admitted to Hampton Institute, Va. (*qv*), at their own earnest desire and the generosity of its large-hearted founder, General Armstrong (*qv*), who soon sent to Dakota Territory for fifty wild Sioux, and added an Indian Department. This experiment was followed the next year by the establishment of a school of similar character, for Indians only, in the abandoned military barracks near Carlisle, Pa., by General R. H. Pratt, who built up at that place the largest, most famous, and in many ways the most successful Indian school in the country. About one thousand pupils at Carlisle and one hundred at Hampton are given a grammar-school education, with a little normal or business training, one half of their time being devoted to agriculture, domestic work, or one of the mechanical trades, taught both for its educational and practical value. Through the "Outing System," originated by General Pratt and since extended to some western schools and reservations, boys and girls are placed in selected farmers' families to work for their board and attend the public school, or during the summer to work for wages, thus learning effectively by association and example.

The eastern or "non-reservation schools," now twenty-six in number and scattered widely over the country, have probably accomplished as much in the way of educating public sentiment and furnishing inspiration and example as in more direct results. Carlisle's brilliant

record in athletics, its football team having met and defeated the teams of some of our leading universities, has done much to attract popular attention to the "educated Indian." The excellent bands of some of the larger schools are likewise a widely popular feature. The great majority of their students, even though not graduates, become self-supporting and self-respecting citizens, cultivating their allotments, making decent homes, or filling responsible positions in the Indian Service, while an ever-increasing minority compete successfully in the various trades and professions in white communities. Of those who fail it should be said that much more is expected of them than is at all reasonable, in view of their meager training, often covering only three to five years, their frequent lack of physical vigor, and the general stagnation of their home surroundings.

Reservation boarding and day schools were first established by the government in 1873. The courses in these are elementary, and in all of the boarding schools the industrial feature has been made prominent, but has only gradually been introduced into the day schools. The evils of appointments made under the political "spoils system" have greatly handicapped the service, these evils having been reduced, but not entirely eliminated, by placing most positions under civil service rules. It is chiefly because of a higher personnel and greater continuity in the service that a comparison between mission and government schools has been generally, though not always, to the disadvantage of the latter. Some of the smaller schools, especially day schools, hampered by poor equipment, inefficient teachers, and a discouraging environment, were by many thought to be almost useless. During the last few years, however, there has been some change in local conditions and a decided change in the official attitude in this regard, and a recent Commissioner of Indian Affairs has recommended the gradual abolition of the non-reservation schools and the development of the simpler and less expensive day-school system, as better adapted to the present needs of the people. The last report of Indian schools gives 343 schools, including mission, with a total enrollment of nearly forty thousand pupils, and involving an annual expenditure of five million dollars. These figures do not include the New York Indians, who are under state control. Eleven thousand Indian children are admitted into the district schools.

A Superintendent of Indian Schools was appointed in 1882, and a force of traveling supervisors some years later. The first supervisor in the field, in 1890, was a woman, and the most practical and successful Superintendent, holding the office for some ten years, was also a woman, Miss Estelle Reel of Wyoming. Each year there are graduates who pass on into higher institutions, such as art, normal, or nurse's training schools, acad-

emies and colleges, so that we have now a considerable number of native teachers and preachers, and some lawyers, dentists, and physicians. A few have succeeded as authors, artists, and lecturers, and we have representatives of our blood in both houses of the national legislature. The results of a generation or two of systematic work are immeasurable, and the best evidence of the Indian's capacity and progressiveness is the list of those who have won recognition and a livelihood in the most exacting and most arduous pursuits of modern life. C. A. E.

**INDICULUS UNIVERSALIS** — A nomenclator or dictionary of the names of things, compiled by the Jesuit, Francis Pomey, similar in its inclusiveness to the *Janua Linguarum* of Comenius, excepting that usually there is not the same amount of descriptive matter that there is in Comenius, i. e. Pomey's book remains strictly a nomenclator. Pomey (1619-1673) became a Jesuit in 1636, and was a teacher in various schools and chiefly at Lyons. He wrote many books, particularly a large French and Latin dictionary, and a small one (*Flos Latinitatis*), a *Pantheum mythicum* (1659), a rhetoric, and *Colloquia scholastica* (1668). The *Indiculus Universalis* (in French and Latin) was published at Lyons in 1667. It went through many editions, and has been issued in several languages, e. g. Italian, Spanish, German, Dutch, and English (See Backer, *Bibliothèque de la Compagnie de Jésus* (1895), Vol. VI, p. 989). An English edition by A. Lovell, M. A., appeared in 1679. F. W.

**INDIFFERENCE.** — See ATTENTION; INTEREST; SCHOOL MANAGEMENT

**INDIFFERENCE POINT** — There are certain experiences which are neutral with reference to their feeling tone, giving neither pleasure nor displeasure. These are said to be at the indifference zone or point. A simple illustration of this fact can be given by observing the transition which takes place in feeling tone when one passes from warm temperature sensations to cold. Between warmth and cold there is a central point at which no pleasure or its opposite is experienced. C. H. J.

**INDIRECT METHOD.** — See DIRECT METHOD.

**INDIRECT VISION** — The field of vision is large, and includes not only those objects which are in the center of clear vision, but also objects which lie around these objects which are most clearly seen. The importance of the field of indirect vision for the individual is that he receives from this indirect field warning of objects that are moving toward the center of the field. However, because of the obscure character of the objects in the indirect field, the individual is not burdened by attention to these indirect objects. He can concentrate attention and experience upon the small number of objects at the center of clearest vision. The structure of the retina is different in the outlying regions. It is more sensitive in these outer regions to differences of light and shadow, and consequently reports all differences in movement of objects; while at the center of vision it is more sensitive to color differences. C. H. J.

See EYE

**INDIVIDUAL.** — See SELF; PERSONALITY

**INDIVIDUAL DIFFERENCES** — Every individual has characteristics which differentiate him from every other member of his race. The biologists have long recognized the importance of individual differences. They commonly use the term "variation" to indicate these departures of individuals from the racial type. When the variations are marked, the term "mutation" is sometimes used to designate the distinguishing characteristic. The two biological terms "variation" and "mutation" are sometimes employed in describing human characteristics. The term "individual differences" is used more commonly to call attention to the fact that along lines which the biologist would neglect there are characteristic differences that are of importance to the educator and to the student of sociology and psychology. Thus the appearance of a very tall or a very short individual would be of importance to the student of physiology and biology, but it would be of relatively small importance to the student of psychology. The appearance of a black-haired family in a light-haired stock would be another important event for the consideration of the biologist, but these physical characteristics are of no great importance to the educator. On the other hand, when an individual appears who is notably deficient or notably strong in his ability to work out number combinations, or to develop skill in one of the arts, we have a type of variation which is of great significance to the educator. These differences may be described as mental variations or mutations. Indeed, it may be said that in mental life we have a sphere of most plastic adaptation and readjustment. The nervous system has been

described as the organ of variation, and consciousness has been described as the sphere of readjustment. When animal forms reach the stage of complexity in which structural readjustment is difficult or well-nigh impossible, the readjustment in function which appears through the use of powers in a great variety of ways takes the place in a measure of the earlier variations in structure which are of prime importance in biology and physiology.

An important question for the student of education is the extent to which individual variations may be affected through educational agencies. The students of heredity have made it clear in recent investigations that there are marked individual differences in ability at the beginning of individual life. The question now arises whether the individual differences which arise from hereditary endowments may be emphasized or overcome through educational practice. There are two schools of thinkers, one of which emphasizes the fundamental hereditary endowments and lays very little stress upon the modifications which can be produced through education. The popular mind, on the other hand, is impressed with the possibilities of modifying the hereditary endowments through educational activities.

The answer to this question has yet to be worked out with the aid of such methods as are described under the topic **TESTS** (*q.v.*) See also **ABILITY**; **EVOLUTION**; **HEREDITY**. C H J

**INDIVIDUAL PSYCHOLOGY** — That branch of psychology which deals with the characteristics that distinguish one individual from another. Much attention has been given to differences in individual imagery. (See **EYE AND EAR MINDEDNESS AND MEMORY**) There are undoubtedly differences in individual inheritance. (See **HEREDITY**) The importance of these individual differences is great in educational practice, as indicated in the adoption of the elective system (*q.v.*) as distinguished from the required course. The whole problem of grading (*q.v.*) is related to this matter of individual differences.

See **ABILITY, GENERAL AND SPECIAL**; **ADOLESCENCE**; **CHILD STUDY**; **PSYCHOLOGY**; also **GRADING AND PROMOTION**

**INDIVIDUAL READING.** — In the teaching of reading in the elementary schools, the traditional practice in assigning lessons is to require the same work of all members of the class. More recent practice separates the class into several groups to each of which a different assignment is made. This is done to give the child an increased interest in preparing

his work at home and reading it aloud to his fellow pupils at school. Under this method the child knows that most of the class will be hearing unfamiliar material, the meaning of which he must make clear to them. Such a method likewise increases the attention of the class, doing away with the listlessness which characterizes children who are compelled to listen to a selection which they themselves have prepared and with which they are thoroughly familiar. H. S.

See **READING, TEACHING OF.**

**INDIVIDUAL TEACHING.** — Any device by which the school program or other organization of classroom instruction allows of increased attention to the special needs of individuals is termed a method of individual teaching. Where the individual adaptation is attained through the teaching of small groups, it is more properly called "group" instruction. Hence the term "individual" teaching more strictly applies to that instruction which attempts to meet the needs of a single child at a time. Such particular care by the teacher may extend from that momentary attention to a pupil which is incidental in class instruction to the use of a supplementary teacher whose chief function is to teach children who require prolonged personal attention. H. S.

See **GROUP INSTRUCTION, SCHOOL MANAGEMENT**

**INDIVIDUALITY** — The idea and fact of individuality are among the most familiar and best known things in experience. They are also among the most difficult to describe and define. Individuality is such a fundamental matter that it can hardly be defined without presupposing itself or giving a purely verbal equivalent, such as the unique, the distinctive to the point of the irreplaceable. An indication of its meaning is given by its logical usage, where it always implies contrast with a kind, sort, or class. This implied contrast also gives an indication of the place where the conception of individuality is important for educational philosophy. School administration and instruction require a certain uniformity of rule and method, these in turn presuppose sameness of character in those dealt with. In so far as individuals are regarded as members, specimens of a class, distinguished from one another by purely external and physical traits. Since, as a matter of fact, there are intrinsic mental and moral differences, the purely uniform, or class, standpoint leaves out of consideration conditions that cannot safely be ignored. The idea of individuality serves as a reminder of these outstanding conditions. It calls attention to those traits which are unique, non-repeatable, which are differential, and which accordingly require special treatment, particular readaptation of general or class methods and standards.

History shows a continual, even if irregular, movement toward individuation, the recognition of the increasing importance of individually distinctive traits. In savage societies, the individual is also lost in the group — in the clan or tribe. Not till a comparatively recent point of historic development do we find individuals possessing rights on their own account in contradistinction from their status as members of a family, guild, class, caste, etc. Their rise from submergence in a class is a part of the growth of democracy as a social principle. From the scientific side, the appearance of the doctrine of evolution has emphasized the importance of individual differences and variations, as against the older notion of the fixed species within which the individual was placed and which exhausted his important or essential nature.

One of the most fundamental of all philosophic cleavages centers in the question of the method of valuing the facts of individuality. Professor James has divided philosophies into those which tend to assume the priority of the whole and to derive the individuals from the whole as its constituent parts or specimen instances, and those which assume the priority of the parts, the individuals, and make the whole secondary, dependent upon the arrangements reached among the individuals. The former philosophies approximate monism in substance and rationalism in method, the latter are pluralistic and empirical. The prominence of the concept of the organic in nineteenth-century idealism is owing to the fact that it seemed to yield a conception for reconciling the otherwise opposed ideas of individual and universal, whole and part. It may be questioned, however, whether the notion of the organic is a solution or only a peculiarly vivid presentation of the terms of the problem. The proper method of dealing with the question is probably suggested by the connection that exists between the common, generic, or class-universal and the facts of stability, order, conservation on one hand, and between individuality and variability, freedom, progress on the other. In a static and finished world, individuality would have no meaning; while a world lacking in universal characters, in characters that make things capable of reduction to classes, would not present any signs of law, permanence, and conservation. For the further educational significance of the term, see EDUCATION; and PHILOSOPHY OF EDUCATION.

**INDO-CHINA** — See FRENCH COLONIES, EDUCATION IN.

**INDUCTION AND DEDUCTION.** — There are two complementary movements of thinking involved in directing inquiry to a well-grounded conclusion. When a perplexity occurs or a problem presents itself, the first step is to

clarify the obscure situation. This consists in such analysis of the situation as indicates a principle, law, or relation. Induction always terminates in an idea or proposition which is general because a statement of a relation, a universal. Deduction is the application of the generic factor to the interpretation, explanation, and organization of specific data. The two movements are complementary because induction terminates in the universal with which deduction sets out, while the validity and scope of the universal is determined by its application, under test conditions, to new facts — this application being deduction.

In Aristotelian logic, syllogism and demonstration correspond to what is now called deduction. The term which was translated into Latin as *deductio* designated simply the method of *reductio ad absurdum*, or the indirect proof of a proposition by showing that its contradictory proposition involved a logical absurdity or self-contradiction. Induction was a method of collecting instances or particular cases, and was perfect when all cases agreed, and formed, therefore, a class as it was imperfect when a number of cases (not all) agreed, so that the most that could be said was that some S is P, or that usually S is P. Perfect induction was known as induction by simple enumeration. After the rise of modern methods of induction, many logicians denied that the method of enumeration was a true case of reasoning, on the ground that it merely summed up in a single statement what was already known, instead of discovering any new truth.

In the sixteenth and seventeenth centuries attacks upon syllogistic logic because of its barrenness and verbal character were widespread. Interest centered in a logic that could be employed to wrest nature's secrets from her, while the syllogism was fitted, as Bacon said, only for argumentation. Agreed in their opposition to the old organon of thought, the new logicians at once divided among themselves. Some, Descartes and his followers, sought the new method in a new type of deduction, others, the British empiricists, in a new form of induction. According to the former school, we should begin by making a *tabula rasa* of all traditional beliefs, and seek for some concepts that are so inherently clear and certain that their meaning cannot be disputed nor their truth doubted. From these most general truths, by combination, further truths were to be established, proceeding by graded steps, so that at no time should any new factor be introduced which was not clearly defined and certain. In this way, reason was to proceed until reaching particular phenomena or concrete events, in space and time. These deduced phenomena would be approximated by actual sensible phenomena, and would constitute the rationality or explanation of the latter. Descartes even went so far as to offer a system of (to him) self-evident first principles, from which, given an original chaotic state of

nature, the whole existing order of the world might be rationally deduced. Stated in the above fashion, the method appears as formal and as fruitless as ever the syllogistic logic had been, but, as matter of content, the whole scheme was conceived in mathematical terms. In effect it was a plea for the application of mathematics to nature. Toward the development of a mathematical science of nature, Descartes himself took the first step by his invention of analytic geometry. And for succeeding men of science—however it may have been with philosophers—deduction has meant mathematical procedure, which, entering upon a brilliant career, became a chief tool of scientific exploration and formulation.

Francis Bacon is popularly reckoned the father of modern induction—an attribution for which Macaulay is probably largely responsible. As a matter of fact, while he made much of induction, the method he proffered under that name is a confused mixture of the older method of cataloguing and the newer method of analysis. Sir Isaac Newton was both the practitioner and the formulator of induction proper, Locke's influence on the philosophic side blending with Newton's. According to Newton, the beginning must always be made with observations, these observations by analogy suggest some force or principle, known on other grounds to exist in nature, though not previously known to be concerned in the phenomena in question. This principle is then to be treated deductively, or mathematically, and thereby phenomena predicted which have not been previously observed, but which must be found if the theory is true. Further observation must then be resorted to to see whether the indicated phenomena do exist. If the actual phenomena agreed precisely with the deduced phenomena, the theory should be accepted until contrary evidence is discovered. So consistent was Newton in his demand for precise corroboration that when the observed astronomical data did not exactly agree with the results he calculated on the basis of his theory, he held the theory of gravitation in suspense until new data enabled him to revise his calculations. For a time the Newtonian and the Cartesian theories of the constitution of the solar system were rivals, but as the immense superiorities of Newton's explanation became more and more evident, the inductive-observational method was as firmly established in the natural sciences of facts, as the deductive in the mathematical.

No important developments in the theory of induction took place after Newton's time until toward the middle of the nineteenth century, when suggestions by Whewell and Herschel were taken up by John Stuart Mill, whose *Principles of Logic* is almost as classic a statement of an empirical inductive logic, as Aristotle's had been of a syllogistic logic. According to Mill, we reason or infer, originally, from particular to particular, from one case to another. This

is due to an inherent propensity to generalize, or to assume that what happens in one case will also happen in other cases. The sole scientific warrant for this belief is the uniformity of nature, which is itself an induction from a vast, literally countless, number of particular observations, where not a single contrary or negating instance is found. This widest of all inductions is, then, the logical ground upon which all other inductions rest.

In the development of his system Mill alternates between two different definitions and treatments of induction, one conventional and rather sterile, the other based on the actual procedure of experimental science. According to the former, induction is the process of inferring that what has been observed to happen in a certain number of observed cases will always happen in cases resembling them. Evidently such a statement is vague. It raises the questions: How great must the number of observed cases be? What is it that really happens in the original cases—no easy matter to determine because of the complexity of natural events. Just what degree of resemblance must exist to warrant belief in the same thing happening in other cases? And how shall we make sure that the required kind of similarity exists? In dealing with such questions, Mill passed over to the idea that the crux of induction is found in the various methods that analyze the observed cases and bring to light within them some unvarying coexistence or sequence of elements. Induction is thus the method of finding in the phenomena some relation which is not directly observable.

Mill never clearly apprehended, however, the transformation which he himself effected in the notion of induction. According to his first and official views, induction simply extends to all cases what is found in some cases. According to the later, his *working*, though not professed, view, it consists in finding out what *really* happens or exists in "some cases." The emphasis has shifted from the mere quantitative collection and mechanical comparison of instances to the qualitative and experimental analysis of the one typical case, or to the few carefully selected cases. Empirical collection of a great number of cases remains indeed of great importance, but as an assistance and safeguard in the selection and analysis of a typical case and in testing the resulting hypothesis, not as furnishing the original premises of an inductive inference.

Educational methods have reflected and have suffered from the divorce of the deductive and inductive phases of reflective inquiry characteristic of the history of logic. The chief error upon the side of the inductive movement is in supposing that the mind begins with a lot of separate, independent objects, such as this, that, and the other river, and then proceeds by mechanical comparison to select the things they statically have in common, and to reject the

qualities not found in them all. As a matter of fact, induction consists in grasping what is *significant*, what is intellectually important, in any one river. Comparison and contrast with other rivers is of value, not in pointing out external likenesses and differences, but in helping to weigh the relative importance of qualities, and to seize upon and to emphasize any property that gives a clew to understanding other features. The trait of generalization found in induction does not primarily have to do with what is common to a number of cases, but with the *law or relation* which is significant in *any* case.

Educationally this means, that it is important to deal with a *single* river basin as a typical case, so as to get an idea of what is important in it, rather than to deal superficially with a large number of river systems. Moreover, the *importance* of any feature means its power to explain other features. Hence what should be emphasized in inductive study is the *causal*, the productive or dynamic factors. These can best be brought out by a thorough study of a river system treated as a type, while comparing a large number of cases without careful analysis of any one case brings into relief only static properties, effects, not causes.

It will be noted that when the inductive method of instruction takes as its object the discovery of causal or explanatory features, it is organically connected with deduction, since the motive of discovering these basic features is to get a principle which may be applied to interpreting and organizing the other facts characteristic of rivers. This application is deductive. On the other hand, the mere selection of properties common to a number of objects throws no light upon *why* they are common, nor does it help explain the traits which, being dissimilar, are eliminated. Hence induction is arbitrarily separated from deduction.

Other errors in the method of instruction due to this mechanical division of induction and deduction are the following. (1) Teaching any subject so that isolated facts are amassed, without using them so that there is gained a view of some inclusive situation in which the different clews are connected and hence significant. (2) Or, when the weakness of this method is perceived, the teacher is content to leave the pupils with only a vague notion of the whole to which the details belong. This vagueness can be expelled (and the special facts made really significant) only as the mind realizes *how* the particulars go together to make up the inclusive whole.

It goes without saying that when induction is isolated from deduction, the latter must also be isolated and hence fail to exercise its proper function. Educational errors of method flowing from this isolation are the following. (1) Beginning with definitions, rules, principles, laws. It may sometimes be pedagogically advisable to *present* a definition or law at the out-

set, especially with older students, but in all cases it should be recognized that this is a psychological device for directing attention to a *problem*, not a statement of a true logical principle. Logically, the general principle or law has no meaning until in the course of dealing with some individual complex situation need has arisen for explaining various particulars by binding them together into a more coherent system. (2) Even when the explanatory principle has been properly reached, there may be failure in the proper use of deduction through not securing its *application* to *new* cases. It is at this point, not at the outset, that the reference to a number of cases becomes most important. When, by a study of a type case, the pupil has become possessed of its principle, or generic nature, this principle must be expanded, clinched, and tested by application to a variety of other cases not previously studied. So far as possible this application should involve not only new observations, but also a factor of experimentation (*q v*). Mathematics, primarily a deductive study, suffers particularly in education from lack of application of its general principles to concrete empirical situation. The application of a mathematical conception simply to other mathematical cases, however adequate in abstract theory, is, pedagogically, simply an elaboration of the principle, not a deductive testing of its meaning.

The prior discussion may be summed up by saying that educational method has lagged behind the development of scientific method. It has tended to remain at the plane of the earlier scientific practices in which induction as dealing with particulars, and deduction as dealing with universals, were separated from each other. Educational method should adapt itself to the change in scientific method, in accord with which reflective inquiry is concerned with complex objects and situations, in which induction serves to discover, by analysis, a relation or principle, while deduction employs that principle synthetically to reconnect particulars into a more comprehensive situation or object.

## INDUSTRIAL ART

**INDUSTRIAL ART.** — See **MANUAL TRAINING**; **DESIGN**, **ART IN EDUCATION**; **ART IN THE SCHOOLS**, **ART SCHOOLS**.

**INDUSTRIAL ART SCHOOLS.** — A type of schools uniting many of the features of art schools and of industrial or technical schools (For detailed discussion of principles underlying the work of these schools, see articles on **ART SCHOOLS**, **ART IN SCHOOLS**; **DESIGN**, **DRAWING**; **INDUSTRIAL EDUCATION**) Instruction in drawing and design forms the basis of the work. Specialized instruction is given along one or more of the following lines: ceramics, designing for special industries, jewelry work, costume designing, decoration, bookbinding, illustration, metal work, etc. These schools form an important part of the educational system in many European countries, notably in Austria, Germany, Switzerland, Great Britain, and France. In Great Britain such schools have been fostered by the national government, which, aroused by the International Exposition held in London in 1851, realized that the country must have well trained designers and craftsmen if its commerce was to be maintained in competition with the artists of foreign workshops. In London, besides the large central industrial art schools, there are numerous local centers under the direction of the County Council and many schools conducted under private auspices.

In the United States, industrial art schools were not developed until after the Philadelphia Centennial Exposition of 1876, when several were established within a few years. The School of Industrial Art of the Pennsylvania Museum was an immediate outgrowth of the Exposition, and to-day is the most important school in the United States devoted entirely to the industrial arts. It is divided into two separate branches — the School of Applied Art, where the enrollment in 1911-1912 was 834, and the Textile School, with 250 students. The Rhode Island School of Design, at Providence, makes a specialty of jewelry and silversmithing, as these are some of the chief industries of the locality. For the same reason the School of Industrial Arts at Trenton concentrates on china and pottery, the principal local industry.

The H. Sophie Newcomb Memorial College of Tulane University, New Orleans, was established in 1887, and has been the pioneer in the South. A pottery was erected in 1901, and Newcomb ware has a recognized artistic and commercial standing. In Cincinnati the Ohio Mechanics' Institute, although established as early as 1828, did not have a day department until 1899. New buildings have recently been erected, and the industrial museum is being developed along art lines, the aim being to make industrial art the special feature of the Institute.

The public schools throughout the United

## INDUSTRIAL EDUCATION

States are developing courses in industrial arts both in the elementary and secondary schools in the belief that this will provide a means for intelligent selection of a vocation and aid in creating an appreciative public. The demand for competent teachers of the industrial arts, particularly for secondary schools, is in excess of the supply. The most important of the normal schools having industrial art courses are Teachers College, Columbia University, New York, Pratt Institute, Brooklyn, N.Y., and the Normal School of Manual Arts at Santa Barbara, Cal.

The following are the most important industrial art schools in the United States: New York State College of Ceramics, Alfred, N.Y.; Maryland School of Art and Design, Baltimore, Md.; Ohio Mechanics Institute, Cincinnati, Ohio; James Milliken University (pottery and metal work), Decatur, Ill.; Evening Drawing School (five years' course for jewelers and silversmiths), Newark, N.J.; Newcomb Memorial College, Tulane University, New Orleans, La. (pottery, embroidery), School of Industrial Arts, Teachers College, Columbia University, New York, N.Y.; New York School of Fine and Applied Art (costume illustration, jewelry, commercial design), New York, N.Y.; Pratt Institute (jewelry, metal work, etc.), Brooklyn, N.Y.; Bradley Polytechnic Institute (metal, wood work, and horology), Peoria, Ill.; School of Industrial Art of the Pennsylvania Museum, Philadelphia, Pa.; Rhode Island School of Design (jewelry and metal work), Providence, R.I.; School of Industrial Arts (pottery), Trenton, N.J.; School of Ceramics of the University of Illinois, Urbana, Ill.

F. N. L.

See **ART**; **ART SCHOOLS**; **ART IN SCHOOLS**, **DESIGN IN DRAWING**; **INDUSTRIAL EDUCATION**.

**INDUSTRIAL DAY SCHOOLS** — See **INDUSTRIAL EDUCATION**.

**INDUSTRIAL EDUCATION** — **General Outline.** — The term "industrial education" may be used in a very comprehensive sense or in a more restricted meaning. In a large way the term includes all education relating to the industries, and in this sense would include instruction in industrial arts in the elementary school, trade and technical instruction designed for the industrial worker, and the professional education of the engineering schools. In common usage, however, the term has come to be used in a more limited fashion as denoting the field of vocational education aimed to meet the needs of the manual worker in the trades and industries, and in this sense is used in the following article. In this conception industrial education has to do with the secondary field beyond the point at which boys and girls leave the elementary school and below that of the college. (See **MANUAL TRAINING** for the

former, and TECHNICAL EDUCATION for the latter.)

The need for industrial education, as far as it is a matter of schools, has arisen since the industrial revolution of the eighteenth century, which introduced the factory system as the universal type of modern industrial organization. During the four or five centuries when the handicraft system of small masters and establishments was the prevailing basis of production, the matter of industrial training was met in a simple, and on the whole, a competent manner within the conduct and organization of trade procedure. (See APPRENTICESHIP EDUCATION; GILD, MEDIEVAL, AND EDUCATION.)

It is true that the gild records of England and the Continental countries disclose many items indicating frequent attempts on the part of masters to take advantage of apprentices through failure to provide competent instruction in their craft, as well as to furnish proper food and findings; and the repeated occurrence of regulations as to fines and other penalties aimed at such abuses, shows very clearly that such conditions were not uncommon. It is also unquestionably true that, particularly in those countries where the period of apprenticeship was of considerable length, as in England and in many trades in France, a large amount of time was consumed in menial tasks of little industrial value to the young worker. On the whole, however, the handicraft system under gild supervision, as trades were then practiced, undoubtedly made for a fairly effective system of industrial training, and this particularly because of three elements inherent in the situation, all of which have disappeared under present conditions. (1) It was distinctly to the master's immediate advantage, with his small staff of workers, which permitted of very little division of labor, to give his apprentice a thorough training in order that he might reap a full labor return during the period of the indenture. (2) The master, being not only employer and merchant, but chief craftsman, working side by side with his assistants, was free to give instruction at such times and in such directions as he saw fit. (3) The fact that the apprentice in the regular order of things expected in a few years to become himself a master must have stimulated his ambition to obtain as broad a knowledge of his craft as possible.

The influence of the factory system upon this situation was not only that division of labor, constantly extended, no longer allowed the learner, if employed to the greatest economic advantage, to obtain a broad experience in all branches of a craft, but, even more important, that the entire relation between employer and learner was changed. The master craftsman, no longer taking direct part in the processes of production, became the capitalist employer, whose first concern is the development of highest immediate productive efficiency. The

learner, on the other hand, entering into such an organization, faces for the most part a wage earning career in which his place will be determined not alone by his abilities and ambitions, but by the particular opportunities afforded him for breadth of experience and for comprehension of these experiences. In such a situation it has ceased to be the immediate interest of the employer to bestow more attention upon the learner than will suffice to make him most rapidly into a productive unit at some process in the range of the establishment. Still less is there economic incentive for the wage earning worker in a commercial establishment to give time and effort to extend the training of the learner. Productive efficiency is the sole aim of the modern organization of industry. For this purpose it is a highly adapted instrument, but education lies outside of this purpose. These latter considerations operate so powerfully upon the case that even in trades representing very little division of labor, the value of apprenticeship training has often fallen to a very low point.

To sum up the situation presented by modern industrial conditions in this connection, it should be noted, first, that grades of skill and the extent to which division of labor is carried vary greatly in different industries. Second, that the typical manufacturing industries employ a large number of workers of low-grade skill, requiring little initial instruction or experience to adapt themselves to their tasks, which often involve only a narrow range of machine operations, and a smaller number of highly skilled workers demanding breadth of experience and trained intelligence for their equipment. Third, that the economic interest of the employer is mainly concerned with the supply of the latter class, and that any measures undertaken by him to train such a class are necessarily based on the prospect of future return and not of immediate profit. Fourth, that such training on the part of the employer involves labor in addition to the purely productive work of an industrial organization, and for that reason an additional element of expense. This element of expense and the extreme mobility of labor under modern conditions, which leave no guarantee to the employer that the learner will remain in his employ after receiving a training, constitute the chief obstacles to the development of adequate measures of industrial training within commercial establishments. To these obstacles is added the fact that, besides skill of hand, modern industry requires in its expert workers increasing knowledge of mathematics, science, drawing, and technical matters in order to insure proper comprehension of new methods and new forces, and for instruction in these branches the organization and personnel of an industrial establishment is not well adapted.

These conditions, in which modern industry

hands the task of competently training high-grade workers within its own organization difficult, expensive, and not assuredly profitable, have brought forward the demand for an outside agency, viz. the school, to assist in the task. The problem thus presented of supplying the deficiencies of training under commercial conditions, and of supplementing this training by additional instruction, is evidently one that must find its solution in particular and varied measures adapted to the needs prescribed by different localities and different industries. From the nature of the case there can be no general solution, but only a multitude of particular solutions.

The precise ends, then, placed before industrial education looked at from this purely economic aspect, are to supply either breadth of practical experience along particular lines, or knowledge leading to the comprehension of technical practice, or both, to youth having opportunities or ambitions to fit themselves as high-grade workers.

To this problem the leading countries of Western Europe have addressed themselves with increasing seriousness for something over half a century, and in the United States conviction as to its importance has been rapidly developing during the last few years. The particular ways in which European countries have approached the problem have been markedly differentiated by racial temperament, institutional development, and industrial conditions. Germany, with her policy of fostering the old trade guilds and their supervision of apprenticeship, has found her particular problem met to a large extent by specialized industrial continuation schools, at first conducted in the evening and now to an increasing extent in the day. These schools have devoted themselves almost wholly to supplementary technical instruction; but in the continuation schools of Munich, Dr Kerschensteiner has introduced trade work both to broaden the commercial routine and to lend zest and point to the other instruction.

One of the chief reasons why the continuation schools fulfill such an important function in German life is the fact that apprenticeship is not only general, but is entered into at the age of fourteen, at the time when youths leave the compulsory *Volksschule*. Another feature that distinguishes the German continuation schools, though shared to some extent with those of Austria and Switzerland, and which marks their seriousness of purpose, is that attendance upon them is generally compulsory until seventeen or eighteen years of age. In the cases where the continuation school classes have been brought into the day, employers are compelled by law to allow their apprentices time for attendance. Compulsory attendance upon the primary school is in this way immediately followed by the compulsory attendance at continuation schools of

all boys, and sometimes girls, who do not attend higher schools.

Germany realizes full well that differentiation and specialization lie at the heart of effective industrial education, and must not only set the keynote of instruction as between various trades, but must be recognized in training the many grades of workers needed for her industrial army. Not only the rank and file, but the foreman, the superintendent, the master, and the technical office clerk must be provided for; and to this end have been developed for those whose ambitions and resources extend beyond the instruction of the continuation schools large numbers of day industrial or technical schools that touch all the important industries of the country. One of the salient characteristics of all these institutions, save an almost negligible few, is that they do not admit beginners to a course of practical work as a substitute for apprenticeship, but require for admission one to four years of experience under commercial conditions and then present courses of scientific and technical instruction bearing on particular industries. Another feature of many of these day schools, which illustrates a contrast between the German point of view and that of some other countries, particularly of the United States, where only large schools or classes are usually considered worth while, is the small size of the student body, a condition the Germans seem contented to maintain, provided the institution secures sound, definite, practical results of importance for its locality or the Empire.

In the efforts to adjust all of these schools as closely as possible to the actual industrial situation, many of the states have removed their control from the Ministry of Education and Public Worship and placed them under the Ministry of Commerce and Industry. The financial assistance afforded to industrial education by the state governments also represents another well defined policy and is a large element in the support of the various schools, being often one half to two thirds of the cost of maintenance. To the towns, however, is generally left the initial burden of buildings and equipment, a task in which they are often assisted by the local chambers of commerce and the guilds. And finally it should be noted that the measures for individual education have the hearty sympathy of the German labor unions, and that these bodies particularly approve the impartial supervision conducted by the State. The whole fabric of German industrial education in this way represents a remarkable example of cooperation between schools, employers, and workers, or, looked at in a larger way, between the state, municipalities, corporations, and the public, and testifies in a striking manner to the solidarity and unity of German life, and the profound belief in the school as an instrument of social efficiency.

Austria, following to a large extent in the

footsteps of Germany, has also placed strong emphasis upon the continuation school and has made attendance thereon compulsory during the period of apprenticeship. The Austrian government, however, because of less satisfactory conditions of apprenticeship than in Germany, arising partly from the many races and nationalities in the country, has given more attention to the development of schools that supply a practical training as a substitute for apprenticeship. These craft schools, or *Fachschulen*, are widely distributed throughout the Empire, and comprehend both purely technical courses and art instruction as applied to the industries, the latter forming a very marked feature of Austrian education. Admission to these schools is nominally limited to those fourteen years old who have finished eight years of the elementary schools, but in outlying districts pupils under this age are allowed to enter. The duration of the courses in these schools is two, three, or four years, as the conditions of the particular industry demand, and the certificate given at the end of these periods is often accepted in place of apprenticeship experience. Among these schools are many dealing with the home or cottage industries — a phase of industrial education to which Austria has given particular attention. Another distinctive feature of governmental activity is the effort to promote and sustain the lesser industries or crafts, which are conducted in establishments of small size. To this end the Department for the Promotion of Crafts, under the Ministry of Public Works, has, particularly since 1908, through industrial museums and other institutions in different parts of the country, fostered exhibitions for handworkers, illustrating technical processes, and lectures upon advanced methods of production. Courses are also provided for those who hope to become masters, not only in technical methods of production, but in the economic principles essential for the successful conduct of a small business. The department goes even further, and assists in the formation of associations of handworkers, to which it supplies modern machinery and tools to be used in common by its members, and for which it requires payment only on long-term loans at a low rate of interest.

Switzerland, with her scant natural resources and consequent economic dependence upon skilled artisanship, has directed her main efforts to the fortifying and advancement of her apprenticeship system. To this end the canton of Zurich passed a law in 1905, the provisions of which have been followed by other cantons, which requires all apprentices to attend a continuation school for four hours weekly, and provides that this period may be taken from the working time. This provision is resulting to a large extent in bringing the instruction time in such schools into the day instead of evening. To further insure high

and progressive standards of apprenticeship training, Zürich and other cantons have made it obligatory upon every apprentice to take an examination at the end of his course, which shall test his technical ability and knowledge of the trade. These examinations are supervised by the State, which also bears the necessary expense, and are conducted largely by trade organizations. At the successful passing of the examinations, a certificate of apprenticeship is issued. Switzerland also gives liberally toward the maintenance of trade and technical schools for advanced training of the more ambitious workers.

The development of industrial education in France presents marked contrasts in some respects to the measures above noted. Apprenticeship in France has been in a more or less unsatisfactory condition ever since the abolition of the guilds or corporations by the National Convention in 1791. Various attempts have been made to effect improvements both by municipalities and by associations, but these have not been particularly successful, and the most distinctive efforts of the French government in the field of industrial education have been directed toward the creation of schools that shall articulate directly with the elementary schools and supply a practical training to take the place of apprenticeship. These schools (*Ecoles pratiques de commerce et d'industrie*) admit pupils at thirteen years of age at the close of the primary school period, and give a three years' course, involving a generous amount of practical training in school workshops. The same feature of building directly upon a previous school training rather than upon required practical experience, characterizes the national schools for foremen, and those for superintendents and managers. In the emphasis placed upon this approach to trade training, the system fostered by the French government stands alone among European countries. Although there are a very large number of drawing and industrial evening classes throughout France, the continuation school has not received the attention or emphasis given to it in the Germanic countries. Attendance upon such schools is voluntary, and their sessions are almost always held in the evening.

**United States** — In the United States the conditions which force attention to the problem of industrial education have only recently appeared. This country has lived over the long industrial history of western Europe in the brief span of little more than a century. Beginning with many of the activities of the hunting and fishing stage, as illustrated in the life of the pioneer and settler, eastern America passed through in rapid succession the agricultural or farming stage, the handicraft period, with its independent town economy, and reached in the closing years of the nineteenth century a highly developed national system marked by immense manufacturing growth.

Throughout this rapid evolution almost to the present time, the great demand for intelligent labor consequent upon the exploitation of the enormous natural resources of the country, has afforded countless opportunities for advancement to the individual workman gifted with superior wit and adaptability. Practical ingenuity and power of quick comprehension and adjustment have often under these conditions been of more importance in winning to positions of leadership and mastership than highly trained skill and technical knowledge. When to this situation has been added an enormous current of immigration that has served to supply not only skilled workmen, but a great army of unskilled and semi-skilled workers increasingly needed for manufacturing operations, it is apparent why for a generation of advanced industrial organization both the American employer and the native-born American workman have remained comparatively indifferent to the need of industrial education.

This period, however, has come nearly to an end, and the stress of international competition and lowered margins of profit make it more and more evident that American industrial development can only be maintained by recourse to old-world methods, and the adoption of comprehensive and effective measures that will insure a competent supply of highly expert workers. What has already been accomplished in the United States is largely the result of private enterprise and philanthropy. Until within a very few years, the public school system has given little or no attention to industrial education and has devoted its energies entirely to general and non-vocational instruction.

*Evening Schools* — The first serious efforts to react upon the industrial situation were represented in the establishment of a number of important evening schools (*qv*), affording instruction in drawing, science, and mathematics. Cooper Union and the Mechanics Institute of New York, Franklin Union, and the Spring Garden Institute of Philadelphia, the Ohio Mechanics Institute of Cincinnati, and the Virginia Mechanics Institute of Richmond were all founded or opened their classes about the middle of the nineteenth century. Such schools, and many others, among which should be mentioned the evening classes of the Young Men's Christian Association (*qv*), have accomplished an important work in supplying supplementary technical instruction to the ambitious young workman in the larger cities. Even in this direction, however, which represents the simplest and least expensive approach to industrial education, the public schools have been slow to follow. Their concern has been almost entirely with general studies, and it is only of late years that differentiated and specialized courses, related to industrial practice, have been introduced in the public schools of a few of the more important cities.

The early work of the evening industrial and technical schools consisted of various lines of drawing, to which were gradually added courses in science, mathematics, and technical subjects. Beginning about 1890, certain of these institutions established practical shop courses in a few of the high-grade mechanical trades, intended to broaden the experience obtained by the student during the day. In a few cases such classes have been incorporated in public evening schools, where they have sometimes performed a valuable practical service in advancing those employed at like occupations during the day, and sometimes have served merely to give a little tool dexterity to the amateur or the clerk.

*Technical Schools* — The next important reaction of organized education upon the industrial situation was that which took place for the most part in the period of mining and railroad expansion following the Civil War, and which resulted in the establishment of many engineering schools or institutes of technology. The establishment of such schools was at first through private foundation, but the passage of the Morrill Act in 1862, by which large land grants were made to the states for the support of instruction in the agricultural and mechanical arts, resulted shortly in the inclusion of engineering departments in most of the western colleges and universities. The development of this type of institution has been widespread in the United States, and has produced an institution equal, and in some respects superior, to anything of its kind to be found abroad. The function of such schools is to produce the engineering and technical expert, the men needed to design industrial constructions, to devise technical processes, and to superintend industrial production. They, consequently, lie outside the scope of this article and are fully treated under Technical Education (*qv*).

*Manual Training* — The first serious agitation for the inclusion of industrial training in the public schools was not for real vocational training, but for the inclusion of manual work in the general course of study as an element of culture and general efficiency. The Manual Training School connected with Washington University, St. Louis, opened classes in 1880, and was rapidly followed by the establishment of manual training high schools in other cities, some on private foundations, but in many cases organized as part of the public school system. From the high school manual training gradually made its way downward into the elementary school, until it is now represented in many cities throughout all the grades. The office of such instruction, however, both in theory and results, is not vocational training, which is always a matter of specialized instruction and self-determined groups, but as a broadening and energizing element in general education. (See MANUAL TRAINING)

*Trade Schools.*—The first important attempt to deal with the problem of industrial training in day schools took the form of a trade school for the building trades. In 1881 the New York Trade School (*qv*) was founded by Richard T. Auchmuty. The founder was an architect by profession, and felt very keenly the small part played by American trained mechanics in the various building trades. Convinced that the apprenticeship system in the building trades was no longer effective, and that modern conditions gave no hope of its revival, he turned to the plan of a trade school as the only solution of the problem. To meet the economic difficulties involved in attendance, the courses in the school are only four months in duration, and only young men between the ages of seventeen and twenty-four are admitted. The aim of the school is to give a knowledge of processes and skill of hand sufficient for immediate practical usefulness, leaving speed and perfected skill to be developed in after experience.

The development of schools which aim to take the place of apprenticeship in whole or in part after this point was very gradual. In the first twenty years after the New York Trade School was founded, only two important institutions were added, viz the Williamson Free School of Mechanical Trades near Philadelphia, and the Baron de Hirsch Trade School of New York. Since the year 1910 some ten or twelve institutions that may strictly be called trade schools have developed in different parts of the country under either public or private support, as well as a number of commercially conducted schools in the building and other trades. In 1907 the trade school entered upon the stage of public administration. In that year the already established Milwaukee School of Trades was taken over by the city under the terms of the industrial education law passed by the Wisconsin legislature. Since that date public trade schools have been opened in Philadelphia, Pa., Portland, Ore., Worcester, Mass., and Indianapolis, Ind.

Certain of these schools — the New York Trade School and the Baron de Hirsch School — represent the short-course type; the others offer courses of two or three years in which practical trade training is supplemented by instruction in drawing and technical practice, and in some cases by science and mathematics. Tuition in such schools is either free or on a nominal basis, a condition made possible either by large endowments or public support. Such schools are still somewhat in the experimental stage. They labor under very severe economic difficulties, first among which is the problem of support presented to the student worker during the period of instruction. Training for the skilled trades in the United States is in common practice restricted to the period above sixteen years of age, and as the great bulk of the youth who will form the mechanics and industrial workers of the country must of

necessity enter upon remunerative work at sixteen or shortly after, the sacrifices necessary to permit attendance at a trade school can be expected only from a comparative few. The second aspect of the economic problem in relation to such schools is found in the large expense of administration, instruction, materials, and physical maintenance in proportion to the number of students that can be instructed. Furthermore, it is only in a few high-grade trades, the full command of which involves extensive subject matter and breadth of experience, that trade school training can claim sufficient advantages over training under commercial conditions to repay its expense. It is, consequently, only in cities representing exceptional concentration of such industries that trade schools can expect support, and it is not yet entirely clear whether the results obtained will prove proportionate to their expense.

In the earlier agitation for industrial training in the United States, the trade school occupied the forefront of discussion and was usually considered as the one institution needed to solve the entire problem, but as the great economic difficulties of attendance for youth and young men who are to become ordinary workmen have come to be better apprehended, it is seen that such institutions can, as far as numbers are concerned, fulfill only a very subordinate office, and that this in the case of the long-course schools will probably be to train a comparatively small number of highly equipped workers in a few of the skilled trades.

*Preparatory Trade Schools.*—Conditions similar to those noted above in the case of England have recently brought forward in the Eastern states the type of school called a preparatory trade school or intermediate industrial school. The situation of the fourteen-year-old boy in the United States is more acute even than in England, inasmuch as the disinclination on the part of employers in the skilled trades and high-grade industries to employ youth below sixteen years of age is much more general. Since the report of the Massachusetts Commission on Industrial and Technical Education in 1906, which pointed out the large numbers of boys and girls in that state who leave school at fourteen before graduation from the elementary school, the demoralizing influences that surround them, and the lack of economic progress made by such children, interest in a type of industrial school that shall aim particularly at the ages from fourteen to sixteen has been steadily growing.

The first school of this type to be established was at Rochester, N. Y., in 1908. Since then a considerable number of schools providing practical work in one or more of the large trade groups, together with related instruction in drawing, elementary science, history, English, shop calculations, accounting, and business forms, have been organized in Massa-

chusetts and the state of New York. Such schools aim to give the advantage of some amount of industrial intelligence and knowledge of shop methods and materials to the boy or girl of sixteen in entering upon industrial employment rather than to impart a trade training.

This type of school points to the fact that forces other than the purely economic enter into the movement for industrial education, and that responsibilities are involved in the conduct of such education beyond those of developing industrial efficiency. The causes that have brought the preparatory trade school into being in the United States are not alone the economic advantage to the industries in preparing better material for entrance therein, an advantage that employers would be quick to perceive yet slow to bring about, but rather the recognition on the part of the public of a social obligation to better the opportunities for great numbers of young persons to enter upon more substantial careers. These schools also serve to illustrate the fact that any institution which enters upon the task of industrial education cannot escape the responsibility of advancing at the same time the training of its students in social and civic efficiency. It is very evident that no school under any form of representative government can command public support or claim a large place as an educational factor in dealing with the education of youth that does not attempt to instruct the individual in his relations to the State as well as in promoting his economic efficiency.

*Part-time and Cooperative Plan* — The two schools just described aim to prepare for entrance into the industries by training beginners, a task only economically justifiable when such training cannot be obtained under commercial conditions. Of late years new types of school — the part-time day school and the cooperative school — that aim to give instruction to the individual at the same time that he is gaining practical experience in the industry, have assumed importance. Such schools do not attempt the entire task of training the learner at any period, but divide the work with organized industry, leaving to industry the practical training, and providing in the school those elements that industry cannot readily supply. These schools, together with evening industrial schools and correspondence schools, bring formal instruction into essentially cooperative relations with industry, avoiding the large financial burden of practical trade training, with its many difficult problems, and undertaking only those lines of instruction with which the school is prepared to deal readily and effectively.

The important practical results of the German, and, in particular, the Munich continuation schools, that have brought instruction into the period of the regular working day, have produced a growing conviction as to the impor-

tance of such schools in the development of industrial education in America. The more individualistic spirit under which industry is conducted in the United States, and the great variety of conditions represented, make progress toward such an arrangement necessarily a very gradual matter, and it will undoubtedly be a considerable time before any general agreement among manufacturers will be reached to allow learners in their establishments to attend industrial schools during the working hours. Nevertheless, the increasing discussion and study of this plan, and the recognition of its important advantages, indicate that its considerable extension may be expected in the near future. Such a plan is more rapidly applied in cities, where the concentration of a few high-grade industries gives a large number of apprentices and learners in particular lines. If such schools are to increase beyond the field of these few skilled trades, it is evident that the problems of instruction become complex and difficult. In the case of low-grade factory industries, where little opportunity for technical instruction is to be found in industrial content, school instruction must necessarily assume other directions and find its opportunity in increasing the social horizon or homekeeping usefulness of the pupil, or in aiding to develop capacity for change of occupation. It is evident that the beginnings of such schools as are represented at Cincinnati and Worcester, Mass., must be necessarily upon a voluntary attendance basis, and many years must obviously elapse before public opinion in the United States reaches the point of authorizing compulsory attendance for a term of years, as is the case in southern Germany.

The cooperative plan by which the students spend half their time at work in industrial establishments and half in school, and which was first developed in the Engineering Department of the University of Cincinnati, has lately been applied to students of high school grade. This plan differs from the part-time plan in some important respects. In the first place the student body consists of enrolled high school students and not of apprentices already employed in commercial establishments. This fact insures a higher grade of academic preparation than is generally the case with apprentices, and the larger amount of time spent in school allows the general education to be carried much further. Encouraging beginnings have been made with this type of school at Fitchburg, Mass., and Cincinnati, Ohio, but it is too early to define its future place. Whether, on the one hand, any considerable number of those aiming at and fitted for regular mechanics work in the trades will be drawn to such schools, or whether, on the other hand, they will develop capacity for training leaders of the foreman and expert type, remains to be seen.

In this same group of supplementary or cooperating schools might be included the cor-

respondence schools (*qv*), which enroll a great number of young men engaged in industrial employment in the United States, and afford instruction by mail in a large number of technical subjects

*Apprenticeship and Corporation Schools* — The apprenticeship or corporation school, which has been developed in several industrial corporations of large size in the United States, is in a sense a part-time school in which both practical training and instruction are given within the commercial establishment. (See APPRENTICESHIP SCHOOLS.) Such a plan, which allows a maximum coordination between all lines of instruction, will probably be increasingly adopted in the case of railroads and other large corporations dealing with high-grade workers, but for the great majority of industrial establishments, such a system is hardly practicable, and division of labor between the employer on the one hand and the public school on the other is the method making for greatest efficiency and economy.

*Secondary Technical Schools* — The middle technical schools of Germany have no exact counterpart in the United States, but the several schools for the textile industry correspond closely to this type. Most prominent among these institutions are the Textile School of the Pennsylvania Museum at Philadelphia, established 1884 and noted for the high grade of its instruction, three state-aided schools in Massachusetts at Lowell, New Bedford, and Fall River, and the Textile Department of the Georgia School of Technology at Atlanta. None of these schools requires previous practical training in the textile industry for admission, but in each school there are a number of mature students with such experience, and the character of the work approximates closely to that of the German schools.

Of late years other technical schools or classes of secondary rank have appeared, such as the day courses in machine design and applied electricity of Pratt Institute, Brooklyn, the Technological High School of the Ohio Mechanics Institute at Cincinnati, and certain courses in the Drexel Institute, Philadelphia, and in the Lewis Institute of Chicago.

*Technical High Schools* — The question whether technical high schools with the same requirements of admission as regular public secondary schools can be incorporated into the American public school system has received considerable discussion of late years. The manual training schools, as above noted, do not contribute trained workers to the industries, and strong arguments have been made toward the conversion of these schools into technical high schools, having the distinct purpose of preparing pupils for industrial leadership, that is, for positions in industrial life requiring skill and technical knowledge, and of greater importance and responsibility than those of skilled mechanics. The serious question facing

such a proposition is whether such results can be secured from a type of school that does not require practical experience before entrance, as in the case of the German technical schools, or provide parallel experience, as in the case of the cooperative schools.

*Legislation* — Laws have been passed in a number of states providing for state supervision of industrial education and in several cases for the establishment and assistance of industrial and trade schools. Massachusetts was the first to act in this direction. In 1906 a State Commission on Industrial Education was created, with power to superintend the establishment and maintenance of industrial schools for boys and girls. The act further provided for the reimbursement to cities and towns of a part of the amount expended for the support of such schools. After two years of trial, the plan of an independent commission was found to be unsatisfactory, and the administration of the law was vested in the reorganized State Board of Education, with provision for a special commissioner to deal with the field of industrial education. Since the reorganization the state board has accomplished very important work in standardizing the various types of schools that come under its control in regard to scope, courses of study, and methods of instruction, as well as in furthering the establishment of a considerable number of schools.

New York State enacted a law in 1909 authorizing the establishment of general industrial schools, trade schools, and schools of agriculture, mechanical arts, and homemaking, and providing for the award to such schools of a certain measure of state support. The disbursement of state moneys to the schools is by the terms of the act placed in the hands of the State Commissioner of Education and made dependent upon his approval of the courses of study maintained. The establishment and conduct of these schools is referred to the local boards of education, but the appointment of advisory boards representing the local trades, industries, and occupations is made compulsory. The duties of such advisory boards are to counsel with and advise the boards of education in regard to the establishment and conduct of the schools.

In 1907 a law was passed in the state of Wisconsin empowering cities or school districts to establish, conduct, and maintain schools for the purpose of giving practical instruction in the useful trades, and placing such schools under the supervision and control of the local school boards. Permission was given to the school boards to appoint advisory committees to assist in the administration of the trade schools, and provision was made for the levy of a special local tax for the establishment and maintenance of such schools. The law was amended in 1909, and the minimum age of entrance to a trade school reduced from six-

teen years to fourteen years for both young men and young women. In 1911 the state passed a number of acts relating to industrial education, which among other measures provides (1) for a modification of the apprenticeship laws of the state by which apprentices shall receive instruction of not less than five hours a week (2) That whenever any evening school, continuation classes, industrial school, or commercial school shall be established for minors between the ages of fourteen and sixteen working under permit provided by law, every such child shall attend such school not less than five hours per week for six months in each year, and every employer shall allow all minor employees over fourteen and under sixteen years of age a corresponding reduction in hours of work (3) That employers shall allow a reduction in hours of work at the time when the classes are held whenever the working time and that of the class coincide (4) That a state board of education be appointed to control the distribution of state moneys under the act

Other states have recognized industrial education through legislative measures to the extent of providing official machinery for the development and supervision of such work, and in still other states investigating commissions have been appointed with the object of ultimate legislation in this direction

**Germany** — The history of industrial education in Germany is intimately bound up with the development of continuation schools and with the system of apprenticeship. Established at first to give instruction in reading, writing, arithmetic, and religion for one or two hours on Sundays, the early continuation school, like its present successor, aimed to secure efficient citizens. The first Sunday continuation school appears to have been founded by the Bishop of Samland in 1569, this system was warmly supported and encouraged by the pietist Spener. Continuation Sunday schools were established by law in Wurttemberg in 1695 to supplement the limited work of the elementary schools, in 1739 they were extended to boys who had left school, in 1810 these schools were authorized not only to repeat the elementary school work, but to give further education. Baden instituted the Sunday school system in 1756, and in 1803 attached continuation schools to the existing elementary schools. In Bavaria the schools were introduced in 1771, and in 1803 attendance was made compulsory for apprentices up to the age of eighteen. Repetition courses were provided for in Prussia by the *Generallandschulreglement* (1763). At the beginning of the nineteenth century the spread of continuation schools was encouraged by town councils and industrial associations, but the interest was soon relaxed as the system of elementary schools became more widely established. The real success of the continuation schools goes back to the Industrial Law passed

by the North German Federation in 1869, by which local bodies were allowed to make attendance at continuation schools compulsory on all workmen under eighteen, while employers were compelled to allow such attendance. This law formed the basis of the later Imperial Industrial Law of 1891 (*Reichsgewerbeordnung*) extended by the law of 1900 —

**SECTION 120** — Employers of labor are required to grant to those of their employees under eighteen years of age who attend a Continuation School arranged by the Government or by the local authority the necessary time for school attendance as prescribed by the authority in question. Classes are only allowed on Sundays if they do not interfere with attendance at Divine Service.

**SECTION 142** — By the by-law of a District or Town Council attendance at Continuation Schools can be made compulsory for male persons under eighteen years. The regulations necessary to enforce compulsory regular attendance at such schools may be fixed by the local authority, and the duties of pupils, parents, guardians, and employers may be so defined as to ensure the regular attendance, the discipline, and the orderly behavior of the pupils. Those pupils are relieved from the attendance at such compulsory schools who attend a *gild* or *Fach* school, provided that such a school is recognized by the superior administrative authority as equivalent in status to the said Continuation School.

**SECTION 150** — A fine of twenty marks (\$5), or, if this is not paid, imprisonment up to three days for every offense, is imposed upon any one contravening any of the above regulations.

The greatest impetus to the development of a system of further education came immediately after the Franco-German war, which was consciously inspired by the desire to enter into the commercial and industrial competition of the world. Continuation schools were made either (1) compulsory by local by-laws, as in Prussia (1874), Baden (1874), Saxe-Altenburg (1889), Saxe-Coburg-Gotha (1874), Anhalt (1874), Brunswick (1878), Oldenburg (1874), Mecklenburg-Strelitz (1873), Schwarzburg-Rudolstadt (1875), Lippe (1874), Reuss J L (1874), compulsory by state law 1900), Alsace-Lorraine (1873), or (2) compulsory by state law, as in Bavaria (1803), Saxony (1873), Wurttemberg (1895), Hesse (1874), Saxe-Weimar (1874), Saxe-Meiningen (1874), Mecklenburg-Schwerin (1905), Schwarzburg-Sondershausen (1874), Waldeck (1895), Bremen (1908), or (3) was left voluntary as in Reuss a L., Schaumburg-Lippe, Hamburg, and Lubeck. In the movement for the spread of compulsory systems the *Deutscher Verband für das Fortbildungsschulwesen* (f 1892) has taken a very prominent part.

Within the last twenty years the development of continuation schools intended for general education rather than specific industrial or vocational training coalesced with another movement for the provisions of industrial education. While the guilds continued in full vigor, the apprenticeship system, with all that it implied in the way of training and moral oversight, could take the place of a state-organized system of vocational education. But the rise of German solidarity and the introduction of national free trade broke the power of the guilds, and some-

thing had to take the place of the apprenticeship system. At the same time the growing complexities of industry which made more and more demands on science, made desirable a training of a type which the individual employer could not give. In 1765 the *Gesellschaft für Beförderung der Künste und nützlichen Gewerbe* (Society for the Promotion of the Arts and Useful Trades) was established in Hamburg, and recommended classes for architectural drawing. Classes were organized, and new subjects were added constantly. In 1865 the society's school was taken over by the city and was maintained as the *Allgemeine Gewerbeschule*. The success of this school led to similar establishments in Berlin (*Handwerkerschule*), and at Hanover, Brunswick, Kiel, Lubeck, Magdeburg, Cologne, Breslau. A *Feiertagsschule für Gesellen und Lehrlinge* (Vacation School for Journeymen and Apprentices) was established at Munich in 1793, giving instructions in the three R's, chemistry, physics, geometry, practical mechanics, law, history, geography, and nature study. The school met with considerable success, and in 1825 an elementary section was added. At Weimar and Eisenach and other towns of Saxe-Weimar free industrial schools (*Freie Gewerbeschule*) arose toward the end of the eighteenth century which laid special emphasis on drawing and geometry. In Saxony town councils and industrial corporations established schools about 1820 for instruction in arithmetic, German, and drawing, and by the law of 1835 continuation schools were empowered to teach such subjects as were not taught in the lower schools, but interest flagged when after 1859 the guilds were deprived of the power to compel attendance on the part of their apprentices. The most continuous development of industrial schools with voluntary attendance has taken place in Württemberg. Beginning in 1818 there were eighteen such schools in 1826, in the preceding year they were placed under the charge of the Royal School Board; instruction, given on Sundays, covered drawing, industrial arithmetic, geography, geometry, mechanics, trigonometry, bookkeeping, and estimating. In 1853 the schools were placed under the Royal Commission for Industrial Continuation Schools, with representatives of the Departments of Education and of the Interior. Evening Industrial Schools were soon added by the Commissioner. They were maintained by local bodies with support from the state. After Württemberg joined the Empire and the *Reichsgewerbeordnung* became applicable to it, many communities made attendance at the industrial improvement school compulsory for apprentices.

*Present Position* — Attendance at continuation schools is now compulsory in twenty-two out of twenty-six German states. Of these, nine still allow the local bodies to make their own by-laws on the subject. Prussia is still among this number, except for the Western section and Posen, where the compulsory system

has been introduced largely for political and administrative reasons. As a general rule compulsion applies only to boys. The rapid and extensive development of elementary education has eliminated the necessity of general continuation schools where the work of the lower school is repeated. Many of these schools, of course, still exist, but they are intended for the class of unskilled laborers. In most states attention is given almost entirely to commercial and industrial education. (The former is discussed under COMMERCIAL EDUCATION.) The reasons for this are theoretical and practical. It has been recognized that the success of instruction depends on concentrating on the vocation of the pupils; this gives unity to the pupils' work and on the other side meets the practical demand for more efficient workmen to assist in the rapid industrial advance of Germany. Hence the aims of these lower industrial schools may be defined as efficiency and citizenship, and in so far as the instruction is not narrowed down to the pupils' vocation, but takes in all its ramifications, such education may serve humanistic and cultural ends. Hence the reformed continuation school requires a different kind of equipment. Workshops and laboratories are now regarded by theorists as important adjuncts of the schools, and have been adopted largely in South Germany. Practice varies, however, and in some systems only theoretical instruction is given in the schools, while the practical work is regarded as sufficient. The value of the new type of industrial continuation schools is shown by the number of students who come voluntarily after the period of compulsory attendance to take work in the classes for journeymen and master workmen.

Where attendance at a continuation school is compulsory on girls, instruction is given to train them as mothers and housewives as well as to render them more efficient at their vocation.

The period of compulsory attendance runs parallel, as a rule, with the period of apprenticeship, that is, from fourteen to eighteen years of age. Within this period a boy must attend school for two or three years. The increasing importance of the industrial continuation schools in the national system is attested by the growing practice of holding the classes during the day. It is recognized that with the increasing importance of the studies, pupils cannot be expected to be fresh at the end of a long day. Thus in Württemberg, Hesse, and Weimar no instruction is permitted after 7 P.M.; in Prussia it is not allowed after 8 or 8.30. The tendency on the whole is now to have special school buildings, made necessary by the need of increased equipment, and to give instruction throughout the day. The number of hours which a pupil is obliged to attend varies considerably; where the instruction is merely repetition of primary work, two hours a week

are sufficient, where an attempt is made to make the education of real social value from four to eight hours a week are given. Instruction extends over the whole of the usual school year, that is, for about forty weeks. Different arrangements are made with different trades and industries, so that attendance does not become an unnecessary burden; thus in some places bakers and confectioners are released from school during the rush of the Christmas holidays, builders and painters, on the other hand, attend mainly during the slack winter season. On the whole, employers are now willing to allow their young employees the necessary time for school attendance, and are beginning to recognize the value of the instruction given, though it is indirectly at their expense for the time being. The greatest opposition is met with in commercial offices, where it is sometimes a matter of difficulty to release the young clerks at certain times of the day. But the school authorities are ready to accommodate the hours of school attendance to the wishes of employers.

The provision of industrial continuation schools has been more rapid than the supply of properly qualified teachers. For the general continuation schools the elementary school teachers were a good source of supply, and even with the addition of new academic subjects, the elementary teachers gave satisfactory service, preparing themselves privately for their special work. The training of teachers of drawing was also of a high standard, though here too the new industrial needs required a different emphasis. The chief difficulty arose, however, upon the introduction of workshops and machine shops into the school and the arrangement of day classes. Two methods of supplying teachers have been adopted. elementary school teachers are given short courses and make themselves acquainted with the practical working of a factory, and master workmen are taken from the factories and given short courses in methods of teaching. In only a few instances have special courses been established for training industrial teachers; the most notable institutions are the training school at Carlsruhe at the Building Trades School, and the courses at the Imperial Technical School at Strassburg. Generally, however, short six weeks' courses are given: in Berlin courses are held in upholstery, baking, hairdressing, book trades, modeling, metalwork, masonry and carpentry, house painting, pottery and anatomy, hygiene and first aid. Visits are made to factories, and instruction is given in tools, machines, and materials. At Dusseldorf a short course of lectures on method is given to teachers selected from the trades. The *Deutscher Verein für Fortbildungsschulen* conducts short courses at Leipzig and Frankfurt a. M. for continuation school teachers. Courses are also conducted by the Prussian Ministry for Commerce and Industry and by the Ministry of

Agriculture for teachers in their respective fields. Another means of training has been the encouragement of journeys of investigation (*Studienreisen*). But it seems highly probable that a more definite system of training will be introduced as the number of industrial schools, fully equipped on the mechanical side, increases, and the candidates will be drawn equally from school and workshops. Further must be mentioned conferences and discussions, as for example a three-day course in technical drawing held at Chemnitz, and conferences on spinning held in the same town.

The administration of industrial continuation schools has in most states been taken out of the hands of the central boards of education. In Prussia the supreme control is under the Ministry of Commerce and Labor, in Saxony the Ministry of the Interior, and in Württemberg the Higher Industrial School Council. The publicly maintained schools are locally under the municipal authorities, which in all cases receive state grants. Generally there are associated with each school advisory councils representing the community, chambers of commerce, guilds, and other industrial societies. Frequently the guilds, and industrial societies contribute to the support of schools, in a number of cases these bodies furnish the necessary tools and mechanical equipment.

The continuation schools may be divided into three broad divisions,—general, industrial, and commercial. The general continuation schools give instruction in the elementary school subjects, and add drawing, civics, and hygiene. The commercial courses are provided for girls as well as boys (See, however, COMMERCIAL EDUCATION). The purely industrial courses are found in the larger towns, where the numbers of employees in different occupations justify such an arrangement organized in groups. Where twenty-five to forty students following one occupation are found, a special course is provided for them. Where the numbers are too small, and for unskilled labor, the pupils are sent to the general continuation schools. Girls may be compelled, and those in commercial occupations are compelled, to attend continuation schools, but usually the period of attendance is not so long as for boys. Courses for girls are, however, not so generally provided. The general courses cover not only the elementary school subjects, but also female handicrafts, household arts, cookery, etc.

One general distinction must be made between North and South Germany. The southern states, on the whole, have been more progressive in the provision of industrial continuation schools and adapting courses to various local industries and occupations, and have been careful to combine theoretical and practical work. In the north the schools as a rule confine themselves to general theoretical courses and leave either employers or associations to

take care of the practical sides. So a comparison can be made between the subjects taught in Prussia and in Bavaria. *Prussia*: German, arithmetic, drawing, business routine, and composition, technology, government, labor laws and conditions, insurance, economics, industrial arithmetic, and practical drawing, according to the various trades, are found generally, and in the larger towns also geometry, trigonometry, algebra, physics, chemistry, electrotechnics, English, history, shorthand, typewriting, bookkeeping, exchange, materials, law, gymnastics, and singing. *Bavaria*: the fundamentals are religion, German, business correspondence, arithmetic, drawing, geometry, nature study, chemistry, materials and bookkeeping, and then the specialized vocational courses. The following courses as arranged in a few representative towns will indicate the organization more clearly.

*Strassburg*. (1) Building groups (stone masons, cement workers, stovemakers, joiners, cabinetmakers, coopers, locksmiths, boiler-makers, tin and copper smiths, upholsterers, etc.) (2) Commercial groups (3) Trade groups (grocers, shoemakers, druggists, errand boys, bakers, butchers, tailors, waiters, cooks, barbers, confectioners, printers). (4) Unskilled labor

*Leipzig*. (1) Unskilled labor (2) Technical groups (3) Combined technical groups where the numbers are not large enough for separate classes (4) Private schools

*Berlin*. (1) Building trades, clerks, metal workers, art crafts, provision dealers, potters, tailors, woodworkers, leather workers, confectioners (2) Private schools (printers, butchers, chimney sweeps, saddlers, painters, barbers, etc.) (3) Unskilled labor

*Dusseldorf*. (1) Unskilled labor (2) Engineers, electricians, mechanics, and watchmakers, plumbers and fitters, building trades, painters, art crafts, printers, turners, gardeners, confectioners, bakers, shoemakers and tailors, upholsterers, decorators, barbers and hairdressers, butchers, errand boys

The Munich system, which, as organized by the School Superintendent, Dr G. Kerschensteiner, has attracted attention throughout the world, deserves more detailed treatment. Here attendance at a continuation school is compulsory for boys up to eighteen, or during their period of apprenticeship; for girls the period of obligatory day attendance is three years. Boys attend from eight to ten hours a week, girls only six hours, although they may attend a voluntary course up to twelve hours a week. An eighth class has been organized in the elementary schools, obligatory for boys, voluntary for girls. This class is intended to bridge the gap between the elementary school and employment, and is preparatory to the industrial courses of the continuation school, the chief emphasis being on manual work. The continuation schools for boys consist of twelve

general and fifty-two trade schools for apprentices. The general courses are attended by errand boys, unskilled laborers, and the groups which are too small for a special school. For girls there are forty compulsory schools giving household training, and twenty-one voluntary schools providing household training, commercial, and industrial courses. A trade or industrial school is established where there are twenty-five apprentices of one industry. Higher divisions are also provided for journeymen and master workmen who attend voluntarily. The schools, with the exception of six, are located in their own buildings; the six exceptions use primary schools. Attached to each school are associations of employers who pay for materials, discuss courses of study, recommend technical teachers, supervise and examine the practical work. The board of each school consists of the headmaster, a member of the city council, and three employers. Pupils attend one day or two half days, forfeiting wages for that period. The teachers are drawn from journeymen, artisans, master workmen, and professional teachers. The expenses of maintaining the school for boys are shared by the state and the city, schools for girls are maintained by the city alone. The curriculum covers drawing and arithmetic, practical and applied to the special industries, tools; machines, physics, chemistry, German literature, religion (up to sixteen); civics, historical development of the specific trades and their interrelations; the individual in relation to town and state; hygiene, gymnastics, and games.

The schools are organized as follows: (1) Commercial classes (2) General continuation classes. (3) Technical or trade classes (turners, druggists, wood carvers, stokers, chimney sweeps, coachmen, saddlers, glovemakers, vatters, coopers, locksmiths, smiths and carriage builders, carpenters and joiners, upholsterers, decorators, stovemakers, watchmakers, engineers, mechanics, plumbers, fitters, bookbinders, printers, photographers, lithographers, barbers, confectioners, house painters, enamelers and gilders, innkeepers, butchers, shoemakers, masons, jewelers and goldsmiths, stucco and stone workers, dentists' assistants, glass and porcelain workers)

The best organized state system is that of Wurttemberg, which in 1907 passed a comprehensive law for the establishment of industrial and continuation schools. Local communities are compelled whenever for three successive years the number of employees reaches forty to establish industrial continuation schools in the first place and commercial schools in the second. All workmen under eighteen must attend such a school for three years, although local by-laws may extend this period to four. Girls' schools may be established locally. Tuition may be charged, and employers may be compelled to pay it. Instruction should be given during the day up to 7 p.m. for 280 hours

a year. Teachers are trained at Carlsruhe for industrial schools, and at Leipzig and other universities for commercial. They are drawn from elementary school teachers and from employees in workshops and factories. All are required to have had practical work in shops for at least two months. The schools do not give practical work, as is the case in Munich. Schools have also been established for women's occupations, and give courses in needlework, embroidery, machine stitching, dressmaking, knitting, correspondence, bookkeeping, and commercial arithmetic. Traveling instructors have for a long time been employed to give short courses in handloom weaving, technical courses (three to twenty-one days), and courses for teachers, masterworkmen, and merchants.

*Day Trade and Industrial Education* — In addition to the system of industrial continuation schools, there exists in Germany a large number of day schools with courses varying from a duration of six months to four years. They are voluntary, and tuition is charged. Schools have been provided by the states, by cities and local authorities, and by private organizations or societies interested in commerce and industry. Generally there is a state subsidy. Here it is proposed to deal with those schools which require only a knowledge of the elementary branches for admission. They aim to furnish not only efficient workmen and servants, but to train master workmen, supervisors, and foremen. In most instances the schools insist that candidates shall have had practical experience in a workshop or factory for one or two years. In some schools attendance takes the place of apprenticeship, in others it is supplementary, and in others again the courses are intended for journeymen. The schools are known as middle or lower technical schools (*mittlere und niedere Fachschulen*), to distinguish them from the higher technical schools and the technical universities, both of which have higher entrance requirements. (See TECHNICAL EDUCATION.)

In Prussia a number of industrial schools (*Gewerbeschulen*) arose in 1828, and met with success; the entrance requirements were raised, and in 1878 they were transformed into *Oberrealschulen*. New schools were established to take their place, e.g. Municipal Artisan School in Berlin, 1880, Iron Workers' School at Remscheid, 1880, Machine Construction School at Cologne, 1881; Spinning Schools at Aachen, Berlin, Cottbus, 1883, Industrial Arts School in Dusseldorf, 1883. In 1884 this type of schools was placed under the Ministry of Labor and Commerce. The development was rapid after 1890, and many municipal schools were taken over by the State. (See *Rep. U. S. Com. Ed.* 1910, pp. 324-329, for list of vocational schools in Prussia.) The following types of schools have been developed: building trade schools for the preparation and training of workmen and foremen in all that pertains to

building, masonry, carpentry, sanitation, drainage, surface improvement, etc. Many officers for city, state, army, and railway administration of buildings and roads are trained. Students are admitted at the age of sixteen, and must have had practical experience. The course lasts four years, and is given as a rule in the winter months.

Schools for machine construction and foundry work give a two years' course for lower technical officers based on common school training and four years practical experience. Many of the lower schools are attached to a higher technical school, and in some cases students are allowed to pass from the one to the other.

A two years' course of study and practice is provided in the Schools for Metal Industries at Iserlohn, Remscheid, Siegen, and Schmalkalden. The entrance requirements are the common school branches. In these courses are trained pattern makers, engravers, locksmiths, turners, printers, etc.

At Hohr and Bunzlau schools are maintained for the ceramic industries. One year of practical work in addition to the common school branches is required for entrance. Courses are given in German and arithmetic drawing and painting, chemistry, physics, mineralogy, geology, ceramic technology, and practical work in the shops.

The textile schools were reorganized in 1896, and afford training for master workmen and young manufacturers in spinning and the allied trades. Traveling teachers are also employed for the country districts where the handloom has still been retained.

There are besides special schools, like the navigation schools, schools of mines, schools for blacksmiths. For girls and young women there are courses in women's handicrafts, machine stitching, white work, laundry, dressmaking, art embroidery, lace making, commercial subjects, and household arts.

The other German states have provided similar schools through the same organizations as in Prussia. Variations occur as demanded by the different industries. In addition to the types of schools referred to above, there are, for example, in Bavaria schools in the wood industries — carving, cabinet making, toys, etc. Such schools are maintained at Berchtesgaden, Oberammergau, Partenkirchen, and Furth. Saxony spends more on industrial schools of all grades than any other German state. At Chemnitz the Technical Institute has several thousand students in the different departments of machine construction, industrial drawing, building construction, textile branches. Each of these branches is also cared for by separate institutions in other towns: textile schools at Reichenbach, Zittau, Plauen, Groschorau, etc.; machine construction at Mittweida, Zwickau, and Hainichen. To the Royal Industrial School at Plauen a museum is attached, with

models, designs, patterns, natural objects, etc. The handworkers' schools aim to give general industrial courses to apprentices and master workers, such schools are found at Dresden, Leipzig, and Bautzen. In Saxony are located a number of national schools maintained primarily by private societies throughout Germany with state or city support. Among these may be mentioned the Tinworkers' School at Aue, the Locksmiths' School at Rosswein, Watchmakers' School at Glashutte, Turners' and Carvers' School at Leipzig, Tanners' School at Freiberg, and the Millers' School at Dippoldiswalde.

The same provision of industrial schools is found in Wurttemberg. At Reutlingen there is the Technicum for the weaving industry, giving instruction in spinning and weaving for manufacturers, superintendents, and master workmen engaged in the textile industries. Other schools in the same field are located at Heidenheim, Laichingen, Sindelfingen, and Sontheim. A state school for skilled mechanics at Schwenningen offers courses in watch and clock making and electrotechnical work. Supported by the state and city, there is at Stuttgart a school for the book printing trades under the auspices of the Union of Proprietors of the Book Printing Establishments.

*Industrial Art Schools.* — Within the scope of industrial education must also be included the industrial art schools, which are nearly all under direct state control. While the artistic side of the industries is by no means neglected, the emphasis in the industrial school falls primarily on the industry involved. The industrial art schools give instruction in the arts as applied to industries, and as a rule are general in scope, and while a few provide courses with reference to special industries, they require a preparatory general course. The schools admit pupils at the age of sixteen, and generally require two years of practical workshop experience. The course extends over two years. While fees are charged, numerous scholarships are offered. Some schools have, in addition to the general course, preparatory courses of two years, pupils being admitted at the age of fourteen. The instruction in the industrial art schools covers the following subjects: all branches of drawing, architectural drawing, modeling, decorative arts, wood carving, painting, enameling, chasing, pattern designing, engraving, art embroidery. Some schools, especially in Bavaria, give courses in glass and porcelain painting. In Prussia there are industrial schools at Berlin (*Königliche Kunstschule* and *Königliche Kunstgewerbemuseum*), at Breslau (*Königliche Kunst- und Kunstgewerbeschule*), at Düsseldorf (municipal *Kunstgewerbeschule*), at Frankfurt a. M. (*Kunstgewerbeschule* of the *Kunstgewerbe-Verein*), Hanau a. M. (*Königliche Zeichen-Akademie*) for training art-jewelers, gold and silver smiths, etc.). The two chief industrial art schools are the *Königliche Kunstgewerbeschulen* at

Munich and Nuremberg. In Saxony there are several special industrial art schools in addition to the *Königliche Kunstgewerbeschule* at Dresden, which also has a preparatory school. At Plauen courses are given in the application of the arts to textiles. The *Königliche Akademie der graphischen Künste und Buchgewerbe* at Leipzig pays special attention to the application of the arts to all branches of the book industry (lithography, woodcuts, engravings, photography, and manifolding). The state *Kunstgewerbeschule* at Stuttgart has preparatory courses in addition to the special courses which are divided into five courses, the arts applied to furniture, models, and woodcarving, decorative arts, chasing, and the teaching of drawing. Similar provisions are found throughout the country.

*England.* — As in Germany, industrial education in England has developed along several different lines. The system of apprenticeship disappeared earlier in England than on the European continent, and, although the industrial and commercial development was more rapid, little was done to promote training until the latter part of the nineteenth century. Classes for adults and young workers were established in the eighteenth and early nineteenth century in connection with the Sunday school movement (*qv*), the Society for the Promotion of Christian Knowledge (*qv*), the Adult Schools (*qv*), and the Mechanics' Institutes (*qv*). But only the two latter movements can be strictly said to have attempted to improve the efficiency of the working classes at their occupations. It was not until 1851 that national action was taken to promote the education of adults. In that year the government made grants to evening schools and classes. Two years after the Exhibition of 1851 the Department of Science and Art was established for the encouragement of instruction in drawing and science. From 1860 grants were given by the department on the result of written examinations; grants were also made for buildings, books, and equipment. In 1872 organized science schools, which offered instruction in science in courses of three years, were established, and might be held by day or night. The Department made grants in respect of the science work at these schools. Many day science schools in 1902 became secondary day schools. Grants have also been made by the Department for instruction in drawing and design. The Technical Instruction Act of 1889 was also administered by the Science and Art Department, and provided for "instruction in the principles of science and art applicable to industries and in the application of special branches of science and art to specific industries or employments." This act remained in force until 1902, and under it local authorities used the powers intrusted to them to provide instruction in almost every subject except the classics. In 1899 the Science and Art Department became

a branch of the Board of Education. Many private associations also supported and encouraged the introduction of scientific instruction mainly into the evening classes. The chief of these was the City and Guilds of London Institute, an association founded in 1878 "for the purposes of all such branches of science and the fine arts as benefit or are of use to or may benefit or be of use to productive and technical industries, especially to commerce and industry generally . . ." The department of technology of the Institute registers and inspects classes in technology and manual training and holds examinations annually in the subjects taught in these classes in the British Empire. Much of the early work in science and the technical branches, encouraged by the different movements referred to above, by various associations, and by the Department of Science and Art, has now been taken over by the local universities and technical schools, and since 1902 by secondary schools. (See ENGLAND, EDUCATION IN; TECHNICAL EDUCATION)

In the present article only those forms of industrial education which are based directly on an elementary school course will be treated. Such instruction is given in higher elementary schools, evening schools (*q v*), and in day trade and technical schools. This classification is, however, incomplete if it neglects the provisions made by employers for giving special trade instruction to their apprentices. (See APPRENTICESHIP AND EDUCATION.) Nor is any account given here of the preparatory courses in the manual arts in elementary schools. (See MANUAL TRAINING.)

*Higher Elementary Schools* — These schools were first recognized by a Minute of the Board of Education (Apr. 6, 1900) as schools organized to give a four years' course to pupils between the ages of ten and fifteen, with a curriculum including practical and theoretical science. Instruction was to be suited to the special circumstances of the districts which they served. By Article 38 (IV) of the Board of Education's Code for 1905, it was to be a condition of the recognition of such schools that "the curriculum must have for its object the development of the education given in the ordinary public elementary schools and the provision of special instruction bearing on the future occupations of the scholars, whether boys or girls." The reason for the establishment of such schools was thus stated by the Board: "The scholar who must at the age of fifteen begin an industrial employment or enter the lower ranks of business needs a course of instruction different from that of the secondary schools, and yet one which is higher in standard and somewhat more special in aim than that given in the ordinary public elementary schools." The number of such schools in the year 1909-1910 in the whole of England and Wales was not more than fifty-one, containing, on the last day of the school year, 10,771 schol-

ars, of whom only 1375 were fifteen years of age or over. The hope that children would be induced to stay and complete a three years' course ending at fifteen years of age has been far from realized. In a number of cases no satisfactory attempt appears to have been made to give the curriculum a bias appropriate to the circumstances and the probable future occupations of the scholars. The Board's conclusion is that "it can hardly be said that the majority of higher elementary schools are in any special degree fulfilling what the Board conceived to be the true function of a school of this type." But, as the Board of Education admit, the comparative failure of higher elementary schools in England does not really indicate the failure of the principles underlying the scheme for their establishment.

As often happens, the central government has made its regulations too advanced, and the higher grants earned by a school definitely classified as a higher elementary school are eaten up by the greater costliness of fulfilling the structural and other conditions required to secure recognition. It is probable that large numbers of schools classified as ordinary elementary schools, *e g* such schools as have been recently organized in London under the name of central schools, are performing quite successfully the functions of a higher elementary school. According to the Report of the Education Committee of the London County Council made in March, 1910, the central schools should "be schools which will give their pupils a definite bias toward some kind of industrial or commercial work, while ensuring that their intelligence should be fully developed, and they should occupy a distinct position from the secondary school. They should avowedly frame their curricula with a view to the pupils leaving at an age between fifteen and sixteen. Their courses should be so framed as to provide for the pupil the best possible equipment for entering upon the industrial or commercial world as soon as he leaves school, while at the same time qualifying him to enter upon a special course of training for some particular industry at a polytechnic or similar institution, if he desires to continue his education further." The central schools were introduced in London in April, 1911. A similar type of school was established in Manchester in the same year.

*Evening Schools* — The development of industrial training in higher elementary schools and in the higher classes of elementary schools may fairly be considered as an attempt to link on directly the elementary with the technical schools. But an intermediate link is felt by some to be, if not absolutely necessary, at any rate desirable. For the fairly large proportion of children who leave the elementary schools at fourteen without reaching the higher classes, and who are quite unfit to take their places in the technical school even of a comparatively low grade, it has long been sought to form a link

by means of evening continuation schools; and certainly the evening continuation schools of Great Britain have done magnificent work, not only for the imperfectly educated, but also for those who have left the higher classes of elementary schools, where no attempt whatever has been made to bear industrial considerations in mind. The impasse caused by the Cocker-ton Judgment (*q v*), which forbade the use of rates for higher education in evening schools, was removed by the act of 1902, which permitted local authorities to support higher education. By the regulations of 1903 evening continuation schools may provide instruction in manual training (wood and metal work), any generalized or special branch of science, including mathematics, home occupations and industries. The curriculum is flexible, and may be adapted to local requirements. Evening technical classes with four or five year courses have also been established in connection with technical schools. They cover instruction in mathematics, drawing, physics, mechanics, machine construction, and some specialized work, *e g* mechanical or electrical engineering.

*Day Trade Schools* — A recent attempt has been made to provide the link by means of certain day schools in various localities popularly described as "trade schools" or "preapprenticeship schools." As a matter of fact there are two grades of such schools (*a*) the preapprenticeship school, (*b*) the trade school proper or apprenticeship school — the avowed object of which is to provide a substitute for the obsolescent apprenticeship system. Of the latter a useful account has been given by Mr. Blair, the education officer of the London County Council, in a paper read before the Imperial Education Conference held in London in 1911. He describes these schools as a development of the day school for boys or girls of thirteen or fourteen years of age, designed generally to provide a more specialized industrial curriculum than is held to be admissible in an elementary school. Their object is to prepare boys and girls to become intelligent workpeople with a chance of rising later, and it is naturally expected that many on leaving the trade school will pursue their education through the avenue of the technical school properly so-called, in many cases, of course, by attendance at evening classes.

As a typical illustration of one of the ten trade schools for boys in London may be taken the School of Building at Brixton, opened in 1908. The course is for three years, and admission is restricted to boys between thirteen and fifteen years of age, who have passed the sixth standard of an elementary school, or its equivalent. "The curriculum, which is common to all students during the first year, and which is looked upon as a probationary period, includes building construction, workshop practice, study of materials, workshop arithmetic and mathematics, experimental science, geometrical and plan drawing and lettering, free-

hand drawing of building details, English literature, history with special reference to industrial changes and the development of public and domestic architecture, geography with special reference to building materials, English composition, and business correspondence. Briefly this is: —

- 8 hours per week workshop practice (general),
- 6 hours per week technical and drawing office instruction,
- 4 hours per week elementary science,
- 10 hours per week English, mathematics, and art applied to building,
- 2 hours per week physical instruction

At the end of the first year the principal advises the parents of the boys attending the school as to the most suitable vocation or craft to select for their sons, this recommendation is based upon any special aptitude shown during the first year, reports from the masters, the character of the boy, and the position of the parents. In the second and third years the courses are divided into two main sections, an artisan course and a higher course for architects, builders, and surveyors, and the development of the timetable in the direction of greater specialization is shown by the fact that in the second year, in place of an eight hours a week course in workshop practice of a general kind, ten hours are devoted in the second year to specialized instruction, and fifteen in the third year. It is clear that the last year's course is hardly distinguishable at all from that of a technical institution properly so called.

Of the six trade schools or apprenticeship schools for girls in London it may be said that they provide instruction in eleven skilled trades for women. "The school hours are from nine to five, Saturdays being free. About two thirds of the school time is devoted to trade work, the remainder being given to art and general education. The trade teaching is in the hands of teachers who have obtained their knowledge of the trade in first-class business houses. As far as is possible in a classroom, workroom conditions are set up. The equipment and arrangement of the room is similar to that of a trade workroom. Workroom methods and trade standards of work are adopted, the chief difference being that, whereas in a workroom many workers may combine to produce one article, in a classroom each girl is responsible for and required to carry through all the processes of the article she makes. Very little formal work is done, as far as possible all completed work is real work made for a particular purpose. The ingenuity of the teachers is called upon to provide sufficient variety of work to provide practice and experience of the various branches of the trade which each girl must learn. A record is kept of the trade work of each girl and of the time spent in producing it."

Of the preapprenticeship type of school for boys, the Trade Preparatory School at Liverpool may be taken as an illustration. The

conditions of admission are much the same as those described above for the London Trade School. "The full course of instruction is arranged to extend over two years, and occupies six hours per day on five days per week for forty-two weeks in the year. The curriculum comprises workshop practice in wood and metal, practical mathematics (including the applications of arithmetic, mensuration, algebra, etc., to workshop problems), practical drawing of simple engineering and building details, with constructive and solid geometry and hand sketching; elementary science (including laboratory work) in mechanics, physics, and chemistry, English (including composition, geography, etc.); physical exercises. The time at present allocated to each of the subjects is as follows —

	HOURS
Workshop practice . . . . .	8
Practical mathematics . . . . .	5
Drawing . . . . .	7
Experimental science . . . . .	5
English . . . . .	4
Physical exercises . . . . .	1
Total . . . . .	30

There is very little specialization of the work even in the second year, and there is no third year, for the boy who is willing to pursue his education further is expected to pass on to a technical school proper."

In the same class of school may be reckoned the schools of domestic science for girls which have sprung up in various towns all over England and Wales, of which the York Terrace School of Domestic Science in Liverpool may be taken as an example (See HOUSEHOLD ARTS). It should be added that there is a tendency to graft on to the general courses in these schools instruction in such branches of woman's work as millinery, upholstery, etc.

The ten trade or apprenticeship schools for boys in London contain 736, and the six London trade schools for girls 620 pupils. There are, as yet, no reliable statistics for the rest of the country, inasmuch as it is very difficult to disentangle the figures for the two types of school, namely, the apprenticeship type and the preapprenticeship type; but it is probable that there are at least fifty schools. These figures, both for London and the country at large, are so small as to show that even as an experiment the day school link between the elementary school and the technical school has hardly passed out of the embryonic even into the infant stage. The costliness of the schools is against them. In London of the 736 boys only 378 pay fees; of the 620 girls only 229 pay fees; and where education is not wholly free, the real measure of public appreciation is not the number of free, but of fee-paying scholars. The net cost to the rates is probably a good deal higher in the schools of the apprenticeship type than of the simpler preapprenticeship type. Thus the net cost to local rates of each girl in

one of the London trade schools for 1909-1910 was £14, 18s. The net cost of a girl in the Liverpool York Terrace school was £4, 8s 10d. The net cost per head of the Liverpool Boys' Preparatory Trade School was £9, 19s.

The trade schools echo the general complaint in England, to be heard in technical institutions of all kinds, namely, that they have not yet won the full confidence and sympathy of employers. But there is reason to believe that the position in this regard is improving partly because employers are becoming more intelligent under the spur of international competition, and partly because the schools are endeavoring more strenuously to turn out young people with the qualifications that square-headed employers are actually found to appreciate, not those that the domed foreheads of the school authorities think they ought to appreciate. It is noteworthy that, in this regard, the success of the girls' trade schools in London has been greater than that of the boys.

This day school experiment, however small, is a valuable one, but it is probable that, until a compulsory system of continuation schools is established the bulk of the real industrial education of the country will continue to be supplied by the higher classes of elementary schools, which are endeavoring to connect themselves up directly with technical institutions, and by the link between the elementary school and the technical institution furnished by the evening continuation school.

In conclusion it may be said that. First, the present situation in England is one of experiment and development. Out of the welter of discussion certain principles are emerging, and in the application of these principles there is infinite variety. But this ferment is all to the good, for it indicates the keen interest of active-minded people, above all of teachers of every grade, in new problems, and something making for the good of the people is more likely to result from the general attitude of inquiry than from any apathetic submission to this authority or that. Second, there is a growing recognition of the truth that it is impossible to have effective industrial education unless the very basis of it is real work, and work which a child or young person recognizes as useful work, such work indeed as makes him realize that he is not only an individual, but also a member of society and a citizen. J G L

**France** — The term "technical education" (*enseignement technique*) has been adopted in France for that education which prepares for industrial and commercial careers. The term "professional education" is sometimes used; this term, however, is too broad, and leads to confusion, since all the institutions which prepare for law, medicine, teaching, etc., are professional schools. In the organization of technical education France is far from having attained to the level of Germany, if it is true that the number of pupils in Germany who attend

industrial courses can be estimated at 400,000 and that of students in commercial schools at 48,000. Great efforts are still necessary to develop a type of education on which the economic future of the country depends. It is especially in the lower grades of technical education that there is room for progress if France is not to be left behind by Germany, and if the so-called crisis in the system of apprenticeship is to be remedied. In the higher and middle or secondary grades of technical education, there is little cause to envy foreign powers. The enrollment in these institutions is 3500 pupils. To these may be added in the intermediate grade the four national professional schools at Armentières, Nantes, Vierzon, and Voiron, with 1327 pupils, the schools of watchmaking at Ouses and Besançon, with 208 pupils; and the fifteen professional schools for boys and girls at Paris with 3116 pupils.

All these institutions, maintained or supported by the State, are controlled by the Minister of Labor and Commerce. The National Conservatory of Arts and Trades was established in Paris at the close of the eighteenth century, and has been reorganized several times. It serves two purposes. It is an industrial museum displaying models and machinery, and is an educational institution. It provides free public courses, which are generally given in the evening and are intended for those who are engaged during the day. Twenty-three different courses are given in the conservatory, which may fitly be called the Sorbonne of industry. The following is a list of the courses: geometry applied to trades, mechanics, machine work, physics applied to arts, industrial electricity, weaving and spinning, civil engineering; art applied to trades; metallurgy and metal work, general chemistry in its relation to industry, agricultural and analytical chemistry, industrial chemistry; chemistry applied to coloring matters, dyeing, and bleaching; chemistry applied to limestone and cement, pottery, and glasswork; agriculture, industrial hygiene; political economy and industrial legislation; industrial economics and statistics; insurance and provident societies, commercial law; social economics; trades unions; industrial and commercial geography.

The Central School of Arts and Manufactures, established in Paris in 1828, became a national institution in 1857, for the training of engineers in all branches of industry. Foreigners are admitted on the same terms as natives. The course lasts three years. There are twenty professors. On leaving, the students receive either a certificate of attainments or a diploma of engineer in arts and manufactures. The holders of this title are much sought after for industrial positions, but have no claim to any official appointment. For government service engineers are trained at the Polytechnic School (*École polytechnique*), and the School of Bridges and Roads (*École des Ponts et Chaussées*).

*National Schools of Arts and Trades (Écoles nationales des Arts et Métiers).* — There are five of these schools (*Châlons-sur-Marne*, *Aix*, *Angers*, *Lille*, and *Cluny*). A sixth school is to be opened in Paris in 1912. Boys between fifteen and seventeen are admitted on an examination which includes written composition and oral tests in orthography, arithmetic, elementary geometry, lineal and ornamental drawing, and algebra. The schools are boarding institutions, and admit about 300 pupils. About three fourths of the pupils hold government scholarships covering tuition and board. A three years' course is given, theoretical and practical, for the industrial training of foremen, managers, capable and trained artisans.

*National Professional Schools (Écoles nationales professionnelles).* — The four professional schools at Armentières, Vierzon, Voiron (established in 1881 and 1882, but opened later), and Nantes (1900) are intended for the training of artisans and foremen in industry, they also prepare for the competitive examination for admission to the National Schools of Arts and Trades. They were formerly under the Minister of Public Instruction, but by law of April 19, 1900, they were placed under the Minister of Labor and Commerce. Instruction is practical and theoretical, and is of the same character as in the watchmaking schools at Ouses and Besançon. They all have courses in iron and wood work, and also specialize in the industries of their district, thus, Armentières has spinning and weaving, Voiron, weaving and silk culture, Vierzon, pottery.

*Lower Schools of Commerce and Industry (Écoles pratiques de Commerce et d'Industrie).* — General preparatory training for industrial, commercial, and agricultural pursuits is given in the Higher Primary Schools (*Écoles Primaires Supérieures*). These offer courses of two or three years, which are based directly on the work of the elementary schools, but are not vocational in any sense. (See further detailed account under FRANCE, EDUCATION IN.) Special industrial schools based on manual work were established by the government in 1880. These *Écoles manuelles d'apprentissage* (Manual apprenticeship schools) were under the control of both the Minister of Public Instruction and the Minister of Commerce and Industry. Their aim was to impart manual dexterity and some knowledge of the science underlying the industries. The dual control (*condominium*) of this type of school proved unsatisfactory, and a reorganization took place in 1892. The manual apprenticeship schools became lower schools of commerce and industry, and were placed under the Minister of Commerce and Industry. They were intended for the training of commercial employees and artisans, and their justification was thus stated: "With few exceptions apprenticeship in a shop no longer exists to-day. It has become indispensable to put at the disposal of business

men assistants who are well prepared and to supply to employers selected artisans." These schools receive pupils up to the age of fifteen. They may be established by municipalities, communes, or departments and receive state aid. In 1910 there were 66 such schools (53 for boys and 13 for girls); 36 of the boys' schools gave instruction in both commerce and industry, 16 in industry, and one in commerce alone. The girls' schools gave the combined courses. There were enrolled 10,350 boys and 2858 girls. In the industrial schools there is a course common to all, — iron and woodwork, while the other courses vary considerably according to the needs of the district, e.g. industrial chemistry and dyeing; wool weaving and cloth manufacture; manufacture of furniture; electricity; gunsmithing; watchmaking, cutlery; printing and typography; etc. In the commercial schools the courses are also distinguished by the local needs. Thus, the choice between two modern languages is determined by the geographical location of the school, the course in merchandise varies according to the local trade; and similarly in the vine-growing districts, the chemistry of wines is taught. In nearly all the schools there is a commercial bureau in which the pupils are made acquainted with samples of prints employed in commerce. The girls receive training to equip them for the home or for employment as artificial flower makers, modistes, corset makers, dressmakers, etc. At the conclusion of the course of three years the graduates receive the *Certificat des Études pratiques commerciales et industrielles*.

In a number of these schools there have been established normal departments which prepare teachers of industry and commerce. It is proposed to establish at Paris a normal school for industrial education.

The efforts of the State are supplemented by municipalities, chambers of commerce, communes, and individuals. In Paris the town maintains seven boys' schools for special industries, for the book industry, *l'École Estienne*; for iron and wood work, *l'École Diderot* and *l'École Dorian*; for furniture, *l'École Boule*; for fine arts applied to industry, *l'École Bernard-Palisse*; for practical drawing, *l'École Germain-Poin*; for the sciences applied to industry, *l'École de Physique et de Chimie*. These schools give general and industrial (theoretical and practical) courses extending over three or four years. In addition there are also eight industrial schools for girls, which prepare for the recognized trades for women, such as tailoring, millinery, flower making, fine lingerie, etc.

A number of schools may be mentioned throughout the country. Attached to the University are the Chemical Institute of Lyons, the *École de Brasserie* (School of Brewing) of Nancy; the Electrotechnic Institute of Grenoble, etc. Due to private initiative or

municipal authorities are the *École La Martinière* at Lyons, celebrated for its special methods of instruction; the Industrial Institute of the North, the Spinning and Weaving School at Lille; the Technical Institute at Roubaix; the Industrial School at Tourcoing, the *École Rouvière* at Toulon, etc. The State assists about 400 technical courses with subventions.

The Schools of Hydrography should also be mentioned, of these there are sixteen, attended by candidates for the merchant marine, and the School of Forestry at Nancy and the *École de Bergerie* at Rambouillet.

As in other countries, chambers of commerce, associations of workmen and employers, and private individuals play an important part in the promotion of commercial and industrial education. Such societies for industrial training include, for example, the Society for Elementary Instruction and the Polytechnic Association (1830) and the Philotechnic Association (1848) at Paris; the Popular Education Society at Havre; the Society of the Rhone for Industrial Instruction at Lyons. Many schools of this type are distinguished from the preceding in that the pupils are received at a more mature age and are already following their occupations, while the courses of instruction tend to be more specialized. Among these schools may be mentioned "the technical schools for masons established by the Paris societies of masons and stone cutters, courses for tailors maintained by the incorporated body of tailors, schools for jewelry manufacture maintained by the jewelers' syndicate." G. C.

**INDUSTRIAL SCHOOLS, 'ENGLISH.** —

A term used in England with special reference to the schools provided for wayward, truant, and criminal children, or children of criminals and drunken parents. They include both day and boarding schools. See for detailed account the article on REFORMATORY EDUCATION.

**INEBRIETY.** — See ALCOHOL, THE USE AND PSYCHOLOGICAL EFFECT OF, INTOXICATION; TEMPERANCE, EDUCATION IN.

**INEQUALITIES.** — If  $a$ ,  $b$ , and  $c$  are positive quantities, such that  $a + b = c$ , we say that  $c$  is greater than  $a$ , or that  $a$  is less than  $c$ . These relations are symbolically expressed thus:  $c > a$ ,  $a < c$ , and these expressions are called inequalities. Inequalities are subject to some of the laws of equations, but not to all of them. For example, if  $a < c$ , then  $a + x < c + x$ ; but  $ax$  is not less than  $cx$ , if  $x$  is negative. The subject of inequalities was formerly treated quite extensively in elementary algebra, and it has an interesting theory. Of late, however, it has been recognized that it is of little value until the subject of limits is reached, and therefore it has but slight treatment in our current textbooks on the algebra of the secondary school. The symbols  $>$  and  $<$  are due to Harriot, an English algebraist who wrote in 1631. At the same period Oughtred, another well known English algebraist, used  $\supset$  and  $\sqsubset$  for the same purpose, and these latter symbols were used by several English writers of the seventeenth century.

D. E. S.

**INFANCY, THEORY OF, IN EDUCATION**

— Infancy denotes, biologically, the phase of immaturity in the development of a function or organ of an organism. It is a more or less relative term, since some one function may be quite undeveloped while others are fully operative. The conception of infancy in contemporary educational theory is also colored by its legal, or better, social sense. Infancy means the period of minority, the period when an individual is legally represented by an adult and is under special protection and supervision. By a natural extension of this meaning, infancy, in education, signifies the entire period in which individuals are protected from the assumption of the full duties of adult life, especially those of economic self-support. So considered, infancy consists of those years in which children are shielded against the impact of economic conditions, in order that their time and energies may be devoted to adequate growth; in other words, the years in which the chief interest is education. Quite obviously, the biological and economic phases of infancy go together. The immaturity of capacity is the cause of economic dependence, while the period of economic dependence preserves

the plasticity of organs that is favorable to continuous educational growth. Thus the conditions favorable to education have been identified with "the prolongation of infancy."

John Fiske is the author of the doctrine of the importance of prolonged infancy. He seized upon the fact that early perfection and high specialization of function are unfavorable to further development, and that they render practically impossible the acquisition of new powers. In some sense, the early perfection of animal instincts and powers is the barrier that precludes learning, and hence development. On the other hand, the incompetency for specialized acts of the human young means a plasticity (*q.v.*) which permits and demands learning — adaptation of capacities to new conditions as these show themselves. Consequently, infancy (of some organ) remains as long as genuine growth, transformation, is possible to a human being. Its opposite is not so much competency of action as arrest of growth, exhaustion of potentiality, of possible assumption of new directions of thought and action.

It follows that infancy is to be conceived positively, rather than negatively, it marks the presence of a powerful and significant resource rather than the mere absence of capacities. Our tendency to conceive infancy in terms of lack, deprivation, impotency, is due to our taking certain specialized adult forms of capacity as our standard, the lack and impotency are purely relative and comparative. If we emphasize the limit of growth which characterizes adult specialized powers (the fact that they evidence the formation of habits that resist readaptation), adult powers are a sign of defect as compared with the mobile, alert ease of adaptation to the new that characterizes infancy. Viewed absolutely, infancy is a power, not an impotency. It is power of growth. Viewed statically, crosswise as it were, immaturity is mere deficiency of development, and till the rise of the biological sciences and of the theory of evolution, it was almost universal to conceive childhood in this negative fashion. Children were simply partial, incomplete adults, the object of education was to hurry them through this period of lack into the full competency of adulthood. Put otherwise, education was a preparation for a future which alone was fully real and significant. But the theory of education substitutes a lengthwise view for this crosswise interpretation, it reveals immaturity as the essence of life itself, the power of continuing development, of renewal, of readaptation to the changing. It represents, so to speak, the evolutionary impetus itself, as against the fixations of capacity for adaptation indicated by matured organs.

The importance of the idea of infancy for educational purposes requires that we note the reflex influence of prolonged infancy upon the social conditions of adult life. It is hardly too much to say, as Mr. Fiske (*q.v.*) also

## INFANCY

first pointed out, that the helplessness of infancy has probably been the chief force in socializing the human race in its progress out of an animal condition. Mutual defense and economic efficiency have been powerful forces in bringing about associations of human beings. Relations of sex have brought about even more intimate and intense associations. But combinations brought about by these forces are relatively transitory and instinctive as compared with those due to the need of the continued care of the young. Although the young of savage peoples are more precocious than those of civilized races, the years in which their dependence demands continued close association are relatively long in contrast with the weeks, days, or hours during which economic and sexual needs hold people together. It is generally admitted, for example, that the change of the marriage relation from a temporary to an enduring form has been chiefly effected by the presence of children, with their long-continued need for support. And this latter motive can hardly have failed to react into industry, changing it from a predatory immediate satisfaction of physical wants as they became urgent into systematized, cooperative, and sustained modes of action. And this is only to say, with respect both to family and industry, that the presence of the dependent young has been a powerful factor in transforming instincts into conscious affections and thoughts. The continued care of children tends to change passionate attraction into tender emotions, into sympathy, into affectionate interest. It also involves foresight, planning ahead, taking into consideration matters broader and longer than the immediate satisfaction of organic appetite. An interesting light upon the education of adults through the necessities due to the presence of children is shed by the rôle which the need of instruction has played in the organization of science. Desire to get knowledge into a form in which it would be available and effective in the training of the less advanced has been an infinitely more powerful motive in bringing together and systematizing knowledge and beliefs than all purely logical motives put together. The need of education has been the chief cause of a survey of experience wider than that required by the narrow immediate personal exigencies of appetite and circumstance. This fact is illustrative of the fundamental intellectual and moral influence due to the presence of infants — that is, of the relatively helpless. In the narrower psychological sense of the term, applying to the period from birth to the end of the third year, the subject is discussed in the preceding article on INFANT EDUCATION.

**INFANT EDUCATION — Historical Sketch** — The education of the child for the first three or four years of its life has among some people received much attention, among others very little. So also has it been in the discussion of education when education has become a matter of philosophical or social consideration.

Among primitive people there exist many customs relating both to the conduct of mother or father, and to the conduct as well as the care of the child. While most of these relate to the care of the body, many of them relate even thus early to the social education. Some of the Zuni or Pueblo Indians even have an initiatory ceremony within three years of infancy. (See PRIMITIVE PEOPLES, EDUCATION AMONG.)

Among ancient peoples whose civilization was of a high order, the Greeks, perhaps, were most acutely conscious of the importance of utilizing the plastic period of infancy for implanting moral and æsthetic ideas and for developing a sound physique. In his *Life of Lycurgus* Plutarch tells us that the Lacedæmonians attached the greatest importance to the rearing of healthy and vigorous children. To this end the girls — future mothers of citizens — received much the same rigid physical and moral training as the boys. The Greek practices concerning infant education are discussed in the article on Greek Education, the ideals and theory are further presented in the articles on Aristotle, Plato, and Plutarch, each of whom wrote in detail upon the subject. Aristotle and Plato also devote much attention to the duties and obligations of the guardians or political officials regarding the education of infants as well as of youths.

With the Romans one finds a type of home training of infants which has become famous. The position of the wife and mother in the Roman household was one of far greater honor and dignity than that of the Greek wife. The newborn infant, far from being consigned "to the mean dwelling of a hireling nurse," was carefully reared by its own mother who divided her time between household concerns and the nurture of her children. If her cares were too onerous, some female relation of irreproachable character was placed in partial charge of the children. The Romans had a just appreciation of the value of imitation in the training of young children. In his treatise called *Brutus*, Cicero maintains that greater atten-

tion should be paid to the language which children daily hear and imitate. The fullest statement of the educational theorist is given by Quintilian. By his time (c 118 A.D.) the emphasis upon intellectual pursuits and the training of the accomplished orator had become pronounced. Hence we need not be surprised to find this prince of educators and stylists not only urging that parents and nurses be cultivated persons, but taking his stand with one Chrysippus, who affirmed that no part of a child's life should be free from tuition. Even though the first three years be allowed to nurses, yet "the minds of children may be imbued with excellent instruction even by them." Quintilian concedes that probably very little can be accomplished in these early years; nevertheless "even studies have their infancy." Yet the little child should by no means be driven to intellectual tasks, but rather be led to find amusement in them.

During the Middle Ages the earliest stage of education, like all other stages, was influenced by a combination of the custom of primitive peoples of the classical civilization and by Christianity. The discussions on early Christian education, CHRISTIAN CHURCH, EARLY EDUCATION UNDER, CATECHETICAL INSTRUCTION, CHURCH SCHOOLS, MIDDLE AGES AND EDUCATION, and related topics give the details for this period. The school ordinances of the German states during the sixteenth and seventeenth centuries reveal, however, the persistence of much of the ignorance and superstition of the primitive period into that late age.

During the Renaissance and the centuries following, ideas and customs with regard to infant education very slowly and gradually underwent modification. In the seventeenth century the swaddling of infants was no longer practiced in England and Germany, although the custom persists in parts of Italy and France down to the present time, despite the vigorous protest of teachers. The nurse becomes a prominent figure in English child life in the reigns of the Tudors and the Stuarts. But the habit of sending children from home to be brought up by foster nurses never gains the foothold in England that it obtains across the channel. The faithful nurse of the Tudor period has been delightfully portrayed in Shakespeare's *Romeo and Juliet*. She it was who cared for the bodily wants of her small charges, and repeated those legendary tales, ballads, and rhymes so dear to the hearts of children. (See NURSERY RHYMES.)

For methods and materials which now began to come in vogue, especially in this early intellectual training, see the article on ABCDARIANS, NURSERY RHYMES, etc. The evil of forcing young children beyond their mental strength existed in the seventeenth century as now, although it was probably not a common practice. Sir John Evelyn, in his *Diary*, proudly writes of his infant son: "At two and

a half old he could perfectly read any of the English, Latine, French or Gothic letters, pronouncing the three first languages exactly." Apparently this infant wonder, who died when he was but just five years old, could decline Latin and French nouns, conjugate most of the regular and irregular verbs, and "had a strong passion for Greeke." Luther and Erasmus (qq.v.) give some consideration to the training appropriate to the very early years. But the most notable writers who consider infant education in the seventeenth century are Comenius and Locke. In his well known work, the *Great Didactic*, Comenius draws a sketch of what he calls the "Mother-School," or "School of the mother's knee." Here he quaintly describes the process by which a very little child may gradually acquire many valuable facts about its world. As the tree very early puts forth the shoots that will later become its branches, so in this first school we must implant in the future man the seeds of all knowledge. Locke (q.v.) is probably the first writer or theorist on education who makes the child the center of the entire process. And for this reason he stresses the physical, moral, and intellectual aspects of education. Of the three the physical is fundamental or basic, but the moral is the most important aspect. The formation of habits of good conduct, which can be begun in the period of infancy, is the chief aim of education. The intellectual aspect is secondary, and comes later.

With the middle of the eighteenth century, the result of Locke's teaching becomes apparent. In the *Emile* of Rousseau (1762) the educational importance of the period of infancy receives its first full recognition. (See ROUSSEAU, JEAN JACQUES, for details.) From the writings of this reformer comes the conception of education as the development of the powers of the individual which makes the physical and psychical growth of the first few years of utmost importance. Extreme as he was in asserting that the nature of the newborn infant is wholly good "as it comes from the hands of the Author of Nature," deteriorating only in the hands of man, he performed an incalculable service in directing the attention of parents and teachers to the "primitive dispositions" of little children, and to the part these should play in determining early home education. This was an age of individualism, and Rousseau would have even the little child emancipated from an unintelligent and cramping tradition, and given his full rights as an individual. In spite of all the inconsistencies and exaggerations so frequently commented on by Rousseau's critics, no one can deny that his influence upon the course of infant nurture and education was enormous.

Pestalozzi and Froebel carried to practical embodiment the more or less theoretic suggestions of Rousseau. From his *Letters on Early Education* it would appear that Pestalozzi was as actively interested in infant

education as his famous successor Froebel. He writes with the utmost earnestness that he despairs of accomplishing all that he hopes and plans for the uplifting of mankind unless the earliest stages of education be provided for. The mother, with her unflinching fount of maternal love, is the agent in whose hands lies the future of human improvement. But how is the untaught mother to direct these powers? Pestalozzi would reply "By developing heart and brain and hands to the true standard of all activity — the spiritual nature of man" (See PESTALOZZI). It was Froebel, however, who stands as the great organizer of the ideas and much of the practices relating to infant education. With Froebel the gospel of the sacredness and almost limitless possibilities of childhood reached its culmination. The original nature of every little child he earnestly believed to be whole and sound, since this nature was but an individual expression of the Divine Unity, of the spiritual life of God pulsating through His highest creation. Therefore every unspoiled child unconsciously and yet surely seeks that which is best. It follows that all early education should be *passive following*, not "prescriptive, categorical, interfering." The details of Froebel's ideas and practices are given under FROEBEL, FRIEDRICH, and KINDERGARTEN. In this connection account should be taken of the more superficial and mechanical scheme worked out in England under the name of Infant Schools (*qv*) chiefly by Wilderspin (*qv*). Yet Rousseau, Pestalozzi, and Froebel were hardly more than frontiersmen in the new domain of child study, staking out the land and indicating the work to be done by their more scientific successors. The modern psychologist and educator, using the suggestions thrown out by these great pioneers, have patiently endeavored to understand, by observation and experiment, the unfolding mind of the infant. Speculation and hit-or-miss empiricism have given place to the painstaking methods of science in the study of the little child, a study upon which the earliest as well as the most advanced education must be grounded if it is to bear wholesome fruit. W G

**Theory** — The term "education" has for so many years been identified with the formal instruction of the schoolroom that the joining of the terms "infant" and "education" seems almost a paradox. However, the present viewpoint is more and more emphasizing the fact that education is adjustment, is change, is preparation for service, the trend being always to ward ideal ends or purposes. With this emphasis on change and adjustment, no period in the child's life offers such evidences of education as do the years before he enters school, those years before his education is supposed to have commenced. If it be possible to point to any one period of four years as the one in which the greatest number of adjustments is made by the

child, when he learns most, this time must surely be the period of infancy. During this interval the child passes from a being with little or no mental life to one surpassing the highest animals in intelligence, showing at least the rudiments of all the human faculties; from a helpless being that makes a few reflex and instinctive movements to one that has control of many voluntary movements which enable him to care for himself, and to manipulate objects and often people to do his pleasure; from a being whose pains are expressed by a single cry to one that experiences many human emotions and desires, capable of expressing himself in symbolic human language, from a being that merely vegetates to one that shows such potential powers that we recognize human capacities.

The importance of this period, which has been emphasized by Preyer, Fiske, Miss Shinn, and others, has been largely lost sight of during the past fifteen years, a fact due to the widespread influence of President Hall and his followers. The adolescent period has been designated as the critical one in the life of the child, hence interest in educational circles has been centering on the development of the individual during the early teens. However, the Montessori (*qv*) movement in Italy, and, more recently, the psychological investigations of Jung and Freud, are again focusing attention on the early infancy of the child. The results of these two investigators in psycho-analysis, although still in the tentative stages, indicate that the desires, emotions, and the mental and physical habits formed in infancy, often before the age of four years, have a very great influence in determining not only the physical status of the child, but also the future emotional and volitional life of the adult. The general trend of development and character given during these early years, even though forgotten, is, they claim, of lasting importance in shaping the final product.

Even those who regard this period as important, however, have offered few suggestions and principles for education; these few are very general and flexible in character. This lack is due to the fact that during this early life the child is in the care of his parents and physician, therefore he has not been subjected to the same close investigation as has been accorded the child of school age. The day nursery is the one institution with its chief interest in children of this age, although to the Montessori schools, wherever found, and to the *écoles maternelles* of France children are admitted at two years, and to the infant schools of England at three. Day nurseries were founded for the care of young children whose mothers were at work; the emphasis in these institutions, especially in this country, has been on the development of good health, the prevention of disease, and on educating the children through play.

The educational principles involved in infant education center around two great topics, whether applied by the mother to the training of the child in the home, or by the teachers in any of the schools mentioned, or by the nurse in the day nursery; these are physical welfare, and the process of habit formation. Of primary importance is the physical welfare, especially during the first year, for upon health must depend not only the habits of this period, but also the intellectual development of later years. During this first year the child nearly trebles his size, a rate of growth far exceeding that of any other period, though it continues rapid for a year or two. In connection with this fact, if one realizes that the proportion of the weight of each of the vital organs to the rest of the body, and the proportion of body surface to weight greatly exceeds what it will be later, and likewise that the automatic machinery governing physiological operations is not yet running smoothly, that about 11 per cent of all children die during the first year and but 2½ per cent during the next two years, is a fact not so surprising. Recent statistics show that "a substantial reduction in the proportion of mortality has taken place even in the large cities, but it is also apparent that the decrease is more marked for children under five than for infants, — a fact which proves that the health problems of the latter have not yet received sufficient attention." Thus, then, is the most critical period of physical development, and all the positive measures to insure normal growth and to prevent disease should be carefully studied and provided by parents.

The factor having most to do with promoting growth and preventing disease is proper feeding. In the early months there is no food which can take the place of the natural one — milk. "Tests made in European countries have revealed the fact that breast-feeding yields the lowest infant mortality, that the use of animal milk causes a larger death-rate, and that the milk substitutes cause the largest death-rates." After the child is weaned, his food must still be fluids, and richer in albuminoids than that of the adult. The way for solid foods must be paved very gradually, for the digestive system is still highly sensitive, therefore easily upset.

Because of the larger radiating surface, and the poorly regulated heating apparatus, the infant is very susceptible to changes in temperature, so that the clothing of the child and the varying temperatures of rooms are important items in insuring good health. To expect an infant to thrive in the hot, dry air of city apartments, where even plants wither and die, is to expect the impossible. Fresh air and sunshine are more important now than at any subsequent time. The furnishings of the nursery and playroom are influential not only in determining the emotional reactions of the infant, but also in predisposing him to certain

æsthetic habits, and should therefore be chosen with care.

Plenty of sleep and lack of intense and rapidly changing stimulation are necessary, as well as plenty of opportunity to exercise the muscles of the body without incurring too great fatigue. One of the most radical changes in recent years in infant education is along this line. The baby used to be considered the plaything of the family, and was always exhibited and "shown off" to guests. While awake, the child was being played with constantly, thus calling for constant change of attention. The forcing of so much violent sense stimulation upon the delicate, growing nervous organism made the baby cross and irritable, induced unnecessary and extreme fatigue, and resulted often in an overexcitable nervous system. The present view is that, though he should be played with and coddled every day, yet much of the time he should be left to himself, to play and to exercise as he pleases, without undue stimulation by adults. Other children later become his companions, and the same principle holds true for the group.

The education of the infant has as its second important factor the formation of good habits. The most important ones, perhaps, are the physiological habits, those of muscular control, — such as talking and walking, — those of perception, and certain moral habits. All education at all times in the life of any individual is conditioned by the capacity of that individual. The instinctive equipment of the infant must determine the habits that can be formed. As some instincts develop later than others, some habits must be begun after the others are well fixed. As the appearance of the instinct, however, depends not only on the stage of physical development reached by the infant, but also upon the environment, it necessarily follows that the presence of an adequate environment at the proper time is a vital factor in the normal education of a child. The formation of a habit on the basis of some instinct, on this level of development, in every case follows the same general course. Blind, uncontrolled movements are made in response to the stimuli of the environment, sometimes many, sometimes few, a proportion of them meet with partial success. The contrast between the two results, and their varying degrees of perfection, tend to develop consciousness in connection with the situation, and the movement which ended in success comes to be deliberately repeated. This repetition of the movement, with the correcting of errors and eliminating useless movements through comparison with a standard, results in a good habit. The importance of the two factors of pleasure from results, and the conscious endeavor to perfect the performance through comparison with a standard, will vary in strength and importance, the latter factor playing a more prominent part as the child

grows older. The duty of the parent or teacher is first, to see that the environment is of such a character that the instinctive reactions will show themselves; second, so to arrange things that good and useful reactions shall meet with success, and harmful or useless ones with failure; third, to make sure that all the elements which form the environment of the developing infant, especially the habits, tempers, and ideals of the adults who surround the infant, shall be of a character worthy to serve as standards toward which his growth may proceed, fourth, to bear in mind that many habits, particularly those in the intellectual and moral fields, need to be progressive, not fixed and left once for all.

In his learning at this stage the infant follows the animal method of trial and "accidental" success; the pleasure which means most to him is physical pleasure, and the pain which really deters is physical pain. Approval and disapproval have considerable influence with the child toward the end of this period, and come to be sought or avoided, at least in the beginning, according to their association with pleasurable or unpleasurable physical conditions. The only motive appealing to the infant is the individualistic one. His only aim is self-advancement and self-gratification. In all children between the ages of two and three the control of this motive is hidden by an apparent unselfishness; this is due to the inability of the child to distinguish between himself and others, his own personality has not yet been differentiated. Because he is not yet a self-conscious being, it makes little difference to him whether he or some one else has the bite or the coddling. This state does not last long, however, for at three, sometimes even before, the consciousness of self appears, and in its emergence the infant shows the individualistic motive in all its strength. To expect a child of three or four to act from any motive other than some form of self-seeking is to expect not alone what cannot happen, but a thing which would be most unfortunate if it did happen. The only method by which the social-minded, altruistic adult can be made is through having the child seek his own well-being alone, with all his heart, mind, and strength. He must learn to know and to be much, before his giving can count for much. Parents and teachers will do well to recognize that this extreme egotism of the young child is both natural and useful; it must be developed, not suppressed. The infant must be won gradually to social interests and motives. During the first three or four years of the child's life it is scarcely possible to make a beginning. In this period to train a baby to be influenced by a word of approval as well as by some reward in the way of food, to want a story instead of a toy, and to be willing to wait for rewards and pleasures instead of demanding them immediately, is to lay a good foundation for future conduct.

Regularity in the physiological processes must be established during the period of infancy. Habits of eating, sleeping, bathing, and evacuation should be fixed. The health of the infant demands at this time the establishment of such habits, and the well-being of the adult, physically and in other ways, may be largely conditioned upon them.

Muscular control comes gradually only, and is evolved from many spontaneous, uncoordinated movements; the baby, therefore, should have wide opportunity to exercise all his muscles, and clothing should not hamper his movements or interfere in the least with circulation or respiration. On a bed or a pile of rugs he can twist, wriggle, kick, swing arms, grasp at the air or anything else, and crow and gurgle, thereby preparing for future muscular control. Such control comes by degrees, first, probably, the large muscles of the arm, then "those of the eyes and head in turning toward sights and sounds, then the body in sitting, the hands in grasping, and finally, near the close of the first year, the legs in creeping, standing, and walking, and the vocal organs in repeating sounds." None of these habits is perfected in this period, but some control is gained, to be perfected and extended during the following period. The habits of walking and talking seldom come together, but a fair degree of control is attained in one, and then attention is called to the other. Walking usually precedes, but if talking is begun early, it may be delayed. Since both of these habits depend on the development of the brain centers in the third level, their appearance is some indication of the development of the nervous system. Undue delay, therefore, in the appearance of activity or in the control of either of these may be a cause for anxiety, indicating a lack of development in higher brain centers. But forcing the infant to walk before the muscles or nerves are ready is unwise, and may result in serious difficulty. After the infant has gained some measure of control of the muscles of arms and legs, he is anxious to use them, and almost any activity will satisfy him, just so he is doing something that does not involve too much fatigue. This, then, is the time to teach him to dress himself, to pick up and put away toys, and to help in many little ways, thus may be established with little effort valuable habits of orderliness and helpfulness.

The development of definite human language from the incoherent babble of the infant has always aroused the interest and wonder of the adult, but the method here followed is that one herein outlined. The babble, involving as it does all the sounds of the language, approaches at times the semblance of a word; the child is then coddled and kissed and made much of. Again and again, his process of accidental success, with subsequent pleasure, takes place, until the child finally deliberately says the word to gain the result; thus grows his control of the

language, imitation of the words and accents of others coming in as aids. At first simple words play the part of whole sentences, for the normal and verbal relations do not exist independently for the young child. For him the object is always acting, for many months, therefore, the verb is neglected, and the noun takes the part of both; this is particularly true of the copula, for gesture and intonation can discharge its function. The other parts of speech appear in the following order: adjective, adverb, preposition, conjunction, and the pronoun at the beginning of the third year. In order that he may once for all learn the correct forms, it is obviously important that the child shall hear good language; this last fact bars from approbation the use of "baby talk," despite the attractiveness it possesses for the adult. Opportunities for verbal expression should be given, and situations presented where needs are satisfied only after the use of such expression. The scope as well as the character of the vocabulary of the child of three depends primarily on the need he has been made to feel for this kind of expression, and the amount of pleasure he has derived therefrom. The language habits formed before school age control for many years.

The relation between the development of language and that of ideas is a very close one, at least to some extent the latter is conditioned by the former. The intellectual life of the child at this age is largely perceptual and imaginative. He is becoming acquainted with himself, with people, with objects. From the mass of unrelated sensory impressions he must evolve unified wholes, possessing certain characteristics. The line of development of this perceptual faculty is suggested by the order of language development noted above. During this process between the third and the fourth year the confusion between the memory of percepts and the images of imagination shows itself. The percepts are still hazy, lacking many essential characteristics, and the images are extremely vivid and interesting, so arises the confusion. The need at this time is for manifold sense experiences, but with opportunity for repetition so that the percept may be fixed with enough variety not to lose the novelty. The broader and more complete the sensory and perceptual experiences of the infant, the greater the possibilities of future intellectual development. Toys afford one of the chief educational means, they should be few, simple, offering much chance for activity, thus offering stimulation for initiative and imagination. With the young child, toys should be changed often, the old ones brought back have the charm of novelty, and so stimulate to further knowledge. Suggestions afforded by the toy congress and by toy exhibits should be of great service to parents in making this stage of the child's development normal and healthful. Before he is four the child

should be asking for stories, these are a very necessary part of his education, alike stimulating the imagination and giving material for the dramatic play. Stories should be chosen carefully, should be within the child's experience, yet with the wonder element prominent. Children of this age are especially interested in other children and in animals, but, whatever the content of the story, it must possess movement, color, life, in order to appeal. Stories told at this time are often the source of the night fears that trouble the majority of children. These fears are due to two factors, the child's lack of experience, which prevents his distinguishing between possible and impossible happenings, and his lack of ability to distinguish between percepts and images. If the story contains anything frightful, the baby is very apt to recall it later, after the darkness has added its mystery, making even the familiar room seem strange. He then may really believe that the bear is under the bed, or that a chance noise is the rattle of the witch's broomstick. As it is the emotional element in any situation that makes the deepest impression on the young child, the fear-producing factor may lie in the telling of the story rather than in its content. The probability of the child's developing night fears at this time is considerably reduced if from infancy he has been trained to go to sleep in the dark, on the other hand, if he is between two and three years of age before he is left in the dark to go to sleep, he will scarcely escape these night terrors, and then, if he is a sensitive, imaginative child, his suffering may be extreme. The other fears which appear in many babies, such as fear of animals, wind, etc., if they are not due to the example of adults, are usually transitory, and can be eliminated by having some definitely pleasurable result connected with the fear-arousing situation.

The period of infancy is the natural time for the establishment of the habit of obedience. It is a natural outgrowth of the relation between the infant and the adult. Obedience must first be given to a personal authority, because pleasure and good results arise from it. Punishment best understood is physical pain, and, a little later, disapproval. The adult should be consistent and moderate in his demands, but the obedience required should be immediate and cheerful. No other habit is of greater importance than this one to the future moral development of the individual. The adult's appreciation of law and his power to command find their source in this habit of obedience. Other moral habits, of self-control in emotions and desires, of cleanliness, of consideration for others, of generosity, loyalty, and truthfulness, must be begun during infancy, the motive appealed to being the same, some form of individual pleasure. The child of three or four who has found out that "it pays" to wait for things, to share with others,

and to obey promptly, is in a fair way to become a social-minded, law-abiding citizen

Briefly summarizing infant education centers about the child's physical welfare, primarily depending on proper feeding, a wise environment including necessarily restful sleep, fresh air, a lack of undue stimulation, judicious "letting alone," and the formation of proper habits as to muscular control, the correct use of language, the regularity of the physiological functions, responsiveness to proper incentives, the development and control of desirable emotions, and the virtues of obedience and self-mastery

**INFANT MORTALITY.** — See MORTALITY AMONG SCHOOL CHILDREN.

**INFANT SCHOOLS.** — The honor of establishing the first infant school is generally ascribed to Jean-Frederic Oberlin (*q.v.*), but the institution from which sprang the infant schools of the British Islands and the *écoles maternelles* of France was established by Robert Owen (*q.v.*). As soon as Owen had obtained complete control of the cotton mills at New Lanark, "a building which may be termed the New Institution was erected in the centre of the establishment with an enclosed area before it . . . intended as a playground." The upper story was intended to serve for a senior school, lecture room, and church, the lower for an infant school. To the infant school children were admitted almost as soon as they could walk. There they were "perpetually superintended to prevent them acquiring bad habits, to give them good ones, and to form their dispositions to mutual kindness." They were taught also "whatever might be supposed useful that they could understand," and the instruction was combined with singing and dancing and as much amusement as was found requisite for health and to render the little ones active, cheerful, and happy. In fine weather they were much out of doors. There was no punishment, and "the children were not to be annoyed with books, but were to be taught the uses and nature or qualities of the common things around them by familiar conversation" and "by sensible signs — the things themselves or models or paintings." The first master was "a good obstinate domine of the old school," but "he could not and would not attempt to adopt what he deemed to be . . . 'new-fangled' ideas." Owen therefore sought among the population of the village (all depending on the mills) "two persons who had a great love for and unlimited patience with infants, and who were thoroughly tractable and willing unreservedly to follow" his instructions. He found a master in "a poor simple-hearted weaver named James Buchanan (*q.v.*), who had been previously trained by his wife to perfect submission to her will," who "loved children strongly" and had inexhaustible patience with them, and who was willing to be instructed. To aid him "a young woman about seventeen years of age, known familiarly among the villagers as Molly Young," was appointed

The New Institution was only one of many plans for forming the younger or reforming

The Infant School at Play.

The Infant School at Work.

the older inhabitants of New Lanark, and, Owen being skillful in attracting attention, these plans became well known both at home and abroad. The Marquis of Lansdowne, Brougham, James Mill, Zachary Macaulay, Joseph Wilson, and other benevolent Englishmen who approved of the infant school, combined in 1818 to set up a similar one at Westminster, and in order that the copy might be perfect they obtained the services of Buchanan as master. He does not seem to have had the originality or the enthusiasm necessary for working well alone, but he inspired Wilderspin (*q.v.*), who had sufficient originality to evolve a new type and sufficient enthusiasm to make it popular. Wilderspin was himself instrumental in establishing a considerable number of infant schools, and his advocacy may have had some influence in inducing the British and Foreign School Society (*q.v.*), the National Society (*q.v.*), and the Irish Commissioners to make such schools an integral part of their systems. His influence in Scotland can be plainly seen. (See STROW, DAVID.)

In 1836 the Home and Colonial Society (*q.v.*) was founded to train teachers for infant schools, and as a leading member of the Committee, Dr Mayo, had resided for nearly three years at Yverdon, the methods of Pestalozzi were inculcated. These must have tended to correct the "bookishness" which was the chief fault of the earlier schools, for Joseph Fletcher, a government inspector who in 1845 examined the schools connected with the British and Foreign School Society, reported that a great improvement had been wrought. The improvement continued, and the Royal Commission appointed in 1858 reported that infant schools "form a most important part of the machinery required for a national system of education inasmuch as they lay the foundation, in some degree of knowledge and in a still greater degree of habits, which are essential to education, while without them a child may contract habits and sustain injuries which the best school will afterwards be unable to correct and remedy." Even then the school for infants was too much a copy of the school for older children, too much was thought of "lessons," and instruction was too often allowed to usurp the place of education. There was a gradual amendment till about 1874, when the introduction of Froebel's principles effected not a reformation but a transformation, surprising alike in its extent and its rapidity. The aims as well as the methods were changed, and the schools, though retaining their old shape, were animated by a new spirit.

*France* — In the only country outside the United Kingdom where it is an integral part of the national system, the infant school may be traced back to the efforts of Mme. de Pastoret. The *salle d'hospitalité* which she founded in Paris in 1801 (see OBERLIN) does

not appear to have lasted long, but when, in 1825, she heard from the Baron de Gérando, who had recently visited London, of the success of Buchanan and Wilderspin, her interest was revived and she resolved to try again. With herself as president and Mme. Millet as treasurer she formed a committee which on Apr. 1, 1826, opened in the Rue du Bac what was called a *salle d'asile*. This excited the attention of M. Cochin, the Mayor of the Twelfth Arrondissement, who persuaded Mme. Millet to go to England to study the plan. He soon followed, and in 1828 after their return the committee opened in the Rue des Martyres a *salle d'asile* on the English model. The same year M. Cochin opened another in the Rue Saint-Hippolyte which by royal command was named after him. To this was attached a normal department under the direction of Mme. Millet. In 1833 the *salle d'asile* was adopted by the government as part of the national system and M. Cochin, published a manual in which he anticipated several of the kindergarten occupations four years before Froebel had opened his first kindergarten (*q.v.*). In 1837 M. de Salvandy (*q.v.*), the Minister of Education, appointed a commission, with M. Cochin as president, to make rules for the conduct of the *salles d'asile* and to draw up a program for the *examens d'aptitude* of their mistresses. Ten years later M. de Salvandy founded in the Rue Neuve Saint-Paul a *maison provisoire d'études*, intended to complete the instruction of persons desiring to devote themselves to the direction or the inspection of *salles d'asile*. This was ultimately called the *École Pape-Carpentier*, after the distinguished lady who for twenty-seven years consecrated her talents and her zeal to its superintendence.

Benefiting by the experience of the English pioneers, the French pioneers strove to avoid the error of making the schools for infants small copies of the schools for older children. The genius of the *salle d'asile*, said Mme. Millet, was to be found in the heart of a mother; and Mme. Pape-Carpentier said that the *salles d'asile* ought to be what M. Carnot decreed in 1848 they should be called, *écoles maternelles*. The old name was resumed after a *décret* of Mar. 21, 1855. This *décret* and the consequential *règlement* fixed the curriculum and the method as well as the name. The curriculum was to include the elements of religious instruction, of reading, of writing, of mental arithmetic and of linear drawing, a knowledge of common things, suitable manual work, hymn singing, moral exercises, and physical exercises. By a *décret* of Aug. 2, 1881, which incidentally adopted once more the name *école maternelle*, the curriculum was modified. It now includes (1) the first principles of moral education; a knowledge of common objects, the elements of drawing, of reading, and of writing; exercises in the mother tongue,

notions of natural history and geography; suitable recitations; (2) manual exercises, (3) singing and graduated "synoptic" movements.

**INFANTILE PARALYSIS.**—Infantile paralysis, or epidemic poliomyelitis, is considered an infectious disease of contagious character. It is caused by a very minute organism which cannot be seen under the most powerful microscope, a germ of the kind called "ultramicroscopic." These minute parasitic bodies can pass through the pores of earthen and porcelain filters, but no difficulty is encountered in the modern laboratory in dealing with the invisible virus in an accurate manner.

The characteristic symptoms are a high temperature, pain in the back and limbs, then suddenly paralysis, generally in the muscles of the leg. The disease attacks especially children between one and five years of age, but adults are also affected. Young children are more likely to be attacked by the disease, but it is more fatal with adults. It attacks chiefly the spinal cord and the brain. The virus is always contained in the central nervous system, and may be absent from the other organs. The virus may enter the nervous system through the blood or by the lymph channels that connect the nasal mucous membrane with the membranes surrounding the brain. The infection may come through the blood by puncture of the skin by an insect, or after swallowing or inhaling the virus into the stomach or lungs, or it may come through the upper nasal mucous membrane. The nose and throat have come to be looked upon as the places where the germs are introduced into the body and expelled from the body. The virus may survive on clothing and the like, and may perhaps be carried by flies and insects.

"While the period during which patients remain infected is not accurately known, there is reason to believe that in most instances the danger is past about four weeks after the onset of the disease, and this period has been adopted as a safe average one of isolation. In exceptional cases of marked severity this period

should be extended somewhat in order to provide a greater security."

There has been in this country an epidemic more or less prevalent since 1907. This is part of a pandemic which has embraced a large part of the world. The prevalence of this disease is an added reason for competent medical inspection in the public schools. It is important that the disease should be detected when it occurs among school children, and it is necessary that other pupils from the family where the case occurs should be excluded from school for a period of four weeks from the onset of the disease.

**INFECTIOUS DISEASES.**—Germ diseases, distinguished from the so-called contagious diseases only by the difference of directness in contact required for transmission. Consequently there exists no real distinction between the two groups. Besides the diseases discussed under the caption Contagious Diseases (*q v.*), the most common school diseases, diphtheria, scarlet fever, measles, whooping cough, mumps, as well as trachoma, infantile paralysis, grippe, meningitis, typhoid fever, and tuberculosis (*qq.v.*), are discussed under separate titles. The general relation of these diseases to the schoolroom is discussed under the caption, Medical Inspection of Schools (*q v.*). So far as their importance in the school is concerned, these diseases may be grouped into two classes. (1) Those diseases for which nearly all cities exclude children, they are: smallpox (now very rare where compulsory vaccination laws are enforced), mumps, chicken pox, pediculosis, ringworm, and scabies. Second, those diseases for which only a limited number of cities exclude children; they are: tonsillitis, tuberculosis, acute conjunctivitis, trachoma, acute coryza, favus, impetigo, and molluscum contagiosum.

All these diseases are infectious, and therefore communicable through the close contact which is inevitable in the usual activities of the schoolroom and schoolyard. Some of them, like mumps, chicken pox, smallpox, acute conjunctivitis, tonsillitis, and acute coryza, are self-limiting germ diseases requiring exclusion of infected children for a definite period. In New York City the period of exclusion for mumps and chicken pox is as follows:—

DISEASE	INCUBATION PERIOD	DURATION OF INFECTION-NESS	PERIOD OF ISOLATION	
			Mild cases	Severe cases
Mumps	14-28	2 weeks Until the removal of the scabs 2 weeks	14 days	28 days
Chickenpox	13-19		14 days	21 days

Exclusion of the other self-limiting infectious diseases is usually for five to ten days according to the severity of the case. (2) The parasitic diseases, such as pediculosis, ringworm, scabies, favus, impetigo, and molluscum contagiosum, are not self-limiting, but, in most cases, they respond readily to proper treatment. Exclusion from school must be supplemented with instruction to the parents for the treatment of these cases, otherwise many children affected with such diseases as pediculosis, scabies, impetigo, or ringworm would be kept out of school for indefinite periods. Two methods have been adopted in different cities for the handling of this problem. One is to have the school nurse visit the home and instruct the mother as to the proper method of treatment. The other method is to send printed directions to the parents with the notice of exclusion. In Everett, Mass., printed directions and a drug store prescription are given to children excluded for parasitic skin diseases, as follows:

*Pediculosis (Lice).* — Directions. Saturate the hair with crude petroleum. Keep it wet for three hours. Then wash the whole head with hot water and soap. Repeat this process on three successive days. Then comb the hair with a fine-toothed comb wet with vinegar. To make the treatment easier and more thorough, have the hair cut short before beginning treatment. While under treatment, keep away from the fire or a lighted lamp. Prescription:  $\mathcal{R}$  Crude Petroleum, 6 oz. M. Sig. Apply to the hair as directed.

*Impetigo Contagiosa.* — Directions: Wash the affected parts with warm water and soap. Apply the ointment morning and night until the disease has disappeared. Prescription:  $\mathcal{R}$  Resorcin, .15; White precipitate, .50, Adipis, q. s. 15.00 M. Sig. Apply A. M. and P. M. until disease is cured.

*Ringworm.* — Directions. Remove the scales with soap and warm water. Dry thoroughly and apply the medicine morning and night until disease is cured. Prescription:

$\mathcal{R}$  Tincture of Iodine, 10, Alcohol, 20. M. Sig. Apply once a day until disease has disappeared.

*Scabies (Itch).* — Directions. Take a bath with warm water and soap, scrubbing oneself thoroughly. Then dry the skin by vigorous friction, and rub into every diseased spot the ointment the prescription calls for. Continue

the treatment daily until disease is cured. Prescription.

$\mathcal{R}$  Sulphur, 7 50, Beta Naphthol, 7 50, Adipis, q. s., 90. M. Sig. Apply as directed. G. L. M.

**INFERENCE** — The process of thinking or reasoning, in so far as it arrives at new facts, conceptions, or truths. It is practically synonymous with going from the known to the unknown, from the uncertain to the established. In its widest use, it covers the entire process of reflection so far as that terminates in discovery. Sometimes, however, the emphasis falls so sharply on discovery that inference and proof are treated as the two antithetical functions of thinking — inference making the leap to the new, the hitherto unknown, while proof tests and validates what is inferred. As demonstrative proof and deduction are usually identified, this limited meaning identifies inference with induction (*q v*). J. D.

See PROOF.

**INFINITESIMAL CALCULUS** — See CALCULUS.

**INFORMAL METHOD.** — It is frequently the case that some technical or conventional fact is taught incidentally, as it occurs in the setting of a content, rather than in the systematic relation that it bears to facts of a similar sort. Thus in the composition period, the teacher merely states to the child that good usage requires "he doesn't" instead of "he don't." No attempt is made to give the child a formal knowledge of the distinction through a complete conjugation of the verb. Thus attempt to keep the facts of the formal subjects, *e g.* arithmetic, grammar, spelling, composition, closely related to their content and use, with a minimum of that distraction which would come through reference to tables, rules, inflections, or other systematic and formal treatments, is called an "informal" method of teaching. It is one species of the incidental method, but refers particularly to instruction given in formalities as occasion requires.

H. S.

See INCIDENTAL METHOD.

**INFORMATION.** — That phase or branch of knowledge (*q v.*) which consists of facts and ideas that have been communicated or transmitted by others, and that are accepted, partially at least, on the credit and authority of others; that branch of learning (*q v.*) that concerns the materials learned from other persons, orally or through books. As will be seen from the definition, information has two marks: a body of cognitive material existing irrespective of its original acquisition and utilization — a ready-made character; and dependence upon

**social transmission** Obviously the two traits belong together. The ready-made character of information is due to its being carried along in the social medium; while by means of the social processes of communication, facts and ideas discovered by any individual are taken up into the general body of knowledge, independently of the conditions of the original discovery.

Without the funding of personal experiences into information capable of separation from the experiences in which it originated, so that it may be acquired by others without the necessity of their repeating the original experience, every generation would be obliged to rediscover everything by its own observations and reflections — which means of course that mankind would be forever engaged in a hopeless struggle to emerge from savagery. Since language is the medium of deposit and transmission, it is natural that language as the storehouse and vehicle of information should be, upon the whole, the chief concern of schooling, and that teaching should be largely identified with the processes of purveying information. On the other hand, the attacks which educational reformers have always found it necessary to make against the domination of schooling by language give evidence of certain dangers lurking in the dependence of individual intelligence upon social acquisitions. The material, not originating in personal initiative and motivation, may easily become a foreign dead load, carried by memory, but not entering in a vital way into personal observations, thoughts, and acts. Such an external second-handed body of information is not only useless, but positively harmful. It weighs down native active tendencies, crushing them, and comes between a person and his use of his natural judgment.

There is, therefore, no problem in education more pressing than the right adaptation of information, as socially communicated knowledge, with these modes of knowledge whose achievement involves active personal response. Without the material of information, individual experience is raw, crude, narrow, untrained. But without the organic assimilation of this material, knowledge tends to be useless pedantry, or learning displayed simply for impressing others by its sheer mass. In the degree in which the body of information remains a special isolated set of facts and ideas not entering freely into everyday direct experiences, it fails wholly of its proper enlightening and directive function. It is suggestive to note that we distinguish between a person of much information and an informed person. The latter is not one who is possessed of a large bulk of second-hand knowledge, but one who is wise, posted, equipped to deal with the matters that concern him. In order that information should be really informing, it is necessary that it be communicated in connection with an active direct experience, not simply in association with other information. It is also necessary

that it be applied to use in some direct activity. For example, scientific information communicated in connection with the undertaking of a laboratory inquiry so as to clarify the question at issue and to direct the experiment intelligently is much more likely to be assimilated into effective knowledge (or "wisdom") than exactly the same material conveyed as just so much matter to be learned by itself. The same may be said about the connection of, say, geographical material with the taking of excursions, there is very much important knowledge about the world that pupils cannot possibly acquire by themselves, but this transmitted material is likely to be fruitful in just the degree in which it is conveyed in connection with those activities in which pupils acquire something through their own observations and reflections. In the latter case, the two modes of knowledge blend and reinforce each other, in the former they remain in mechanical juxtaposition, and their isolation prevents the due efficiency of both.

J D.

See KNOWLEDGE.

**INFORMATION TALKS** -- The contemporary emphasis on individual study by children, and the use of the method of development by teachers have in great degree neglected the fact that there is a great deal of accumulated information that the child does not have to discover for himself or have taught him by the slow inductive methods of teaching. To overcome this defect, information talks are now frequently given by the teacher, the function of which is to supplement the knowledge that the child has gotten for himself in a vital but more or less fragmentary way. Such information talks do not do away with individual study or developmental teaching, they complement it. They usually follow rather than precede the more individualistic modes of teaching, the exception arising when the teacher wishes by way of preliminary to develop interest in a situation or to give a setting to the problem under consideration. These information talks are for the most part short, appearing here and there as needed in the class period. In elementary school practice they are the correlatives of the university lecture, undergoing such necessary modification and subordination that a different name is applied. In the best pedagogical sense, information talks are a sane and useful application of the lecture method.

H S

See LECTURE METHOD; TEACHING.

**INGOLSTADT, UNIVERSITY OF, BAVARIA** -- An institution founded in 1472 by Duke Lewis the Rich of Upper and Lower Bavaria, on the model of the University of Vienna. The Papal Bull of Pius II authorizing the establishment of the university was dated 1459, but instruction was not actually begun until thirteen years later. The institution

consisted of four faculties, of which the faculty of philosophy early assumed the chief importance. During the Reformation Ingolstadt sided with the Catholic party, one of the most prominent members of the teaching staff being Johann von Eck, who replied to Martin Luther's ninety-five theses, thereby paving the way for the Leipzig disputation between himself and Luther in 1519. At the close of the sixteenth century the university attracted a large number of students, Jesuit influences being paramount from the middle of the sixteenth to the eighteenth century, *i.e.* to the suppression of the Jesuit order in 1772. The foundation for the present faculty of political science (University of Munich) was laid in 1799 by the establishment of an institute of cameralistics, which comprised a series of subjects from the fields of jurisprudence, natural science, political economy, statistics, technology, agriculture, and forestry. In due course of time technology and agriculture were transferred to the technical school at Munich, but the subject of forestry is to this day included in the faculty of political science of the University of Munich. In 1800 the university was transferred to the city of Landshut, and from there to Munich (*q.v.*) twenty-six years later. Ingolstadt is also the seat of the first Jesuit college founded in Germany (1555).

LEXIS, W. *Das Unterrichtswesen im deutschen Reich*. Vol I, pp 452-454 (Berlin, 1904)

**INHIBITION.**—A term applied to two groups of phenomena. the one psychological, the other physiological. Psychological inhibition consists in the conflict of parts of the content of consciousness, and the partial or total suppression of one by another. Awareness of pain, for example, may be inhibited by other sensations. The soldier frequently suffers severe wounds of which he remains unconscious because of the inhibiting influence of emotional experience. In the hypnotic state one of the most obvious phenomena is the inhibition of certain kinds of consciousness by others which, perhaps, have been suggested by the hypnotizer.

Physiological inhibition consists in the partial or total suppression of one physiological process by another or others. The phenomenon is best known in connection with the functioning of the nervous system. There are certain specifically inhibitory nerves, as for example the vagus, whose function is the regulation of certain organic processes by suppression or depression. The activity of the heart may be inhibited by stimulation of the vagus. But the cases of inhibition which result from the functioning of inhibitory nerves or centers, if such exist, are few and unimportant in comparison with those which appear to be due to the conflict or competition of impulses within

the nervous system. The appropriate reflex of the leg of the frog to stimulation of the foot may often be inhibited by simultaneous stimulation of the other leg. As Sherrington says, "the most striking thing that we know of inhibition is that it is a phenomenon in which an agent, such as in most cases excites or increases an action going on, in this case stops or diminishes an action going on." R. M. Y.

**INITIATIVE** — A term denoting originality and independent force as factors to be maintained and secured in education. Initiative is etymologically connected with the word "initial"; namely, something at the beginning or outset. It thus refers to ability to originate, to undertake independently, some desired line of action. It is opposed to mere docility, passiveness, imitativeness, and other conceptions that denote dependence upon others in entering upon a new course of action. The demand for initiative as an indispensable part of the educational aim is coincident practically with the growth of democracy (*q.v.*). In a feudalistic society personal initiative is undesired with respect to the masses of men, what is wanted is that they should readily subordinate themselves to the carrying out of the demands and ideas of others. The proper adjustment of the personal initiative required by a democracy on its social and political sides to the conditions of industrial employment and wage-earning involved in the capitalistic régime is a problem still to be solved, or even seriously considered, yet it is the heart of the question of industrial education. J. D.

See ACTIVITY; INDIVIDUALITY, FREEDOM

**INJURED, FIRST AID TO.**—Instruction in first aid as it is ordinarily given is of value because of its health-preserving or life-saving possibilities. But in addition to this utilitarian quality, such instruction in the hands of the well-informed and skillful teacher may be given intellectual and scientific qualities. All rational first-aid treatment is based on a scientific knowledge of the relation between anatomical structure and physiological function, and between pathological cause and morbid effect. These relationships are most easily and successfully brought out in those courses where instruction in first aid is made an essential part of a general scheme made up of instruction in hygiene and physiology. Instruction in first aid may then easily be educa-

tional as well as utilitarian. It is, however, chiefly and most seriously valuable because of its utility.

In planning a course of instruction in first aid the teacher must take into account the maturity of his pupils. It is obviously useless as well as dangerous, to instruct young children in the use of poisonous antiseptics, and then expect them to make any practical use of the knowledge they may have gained through such instruction.

Another important consideration is the applicability of the instruction given to the daily affairs of the individual who is receiving the instruction.

Instruction in first aid should always be graphically illustrated and demonstrated in every practicable way. In addition, the individual receiving such instruction will profit a great deal more, if he is permitted to do under supervision the minutest details of what he is being taught. The application of simple bandages, the construction of a sling, the technique of resuscitation of the partially drowned are samples of procedures that each member of the class should be required to do step by step under careful supervision. In other words, the teacher of first aid will do well to employ appropriately the various practical educational methods which he finds advantageous in his other classroom or laboratory instruction.

Instruction in first aid should emphasize the need for medical help in appropriate cases. Serious consequences may be avoided, if the non-medical attendant is not so sure of his own ability as to neglect to call in expert help.

*Scope of Instruction* — The scope of a course in first aid should include instruction concerning preventive and protective measures, emergency treatment, and emergency prophylactic treatment appropriate to the maturity, intelligence, and education of the individuals under instruction and applicable to the conditions under which they are most likely to have practical use for such instruction.

*Preventive and Protective.* — Instruction in swimming, diving, rescue, and resuscitation manœuvres; management of the rowboat and canoe, danger of the undertow, seapuss, waves, breakers and waves in the wake of the passing steamer; the avoidance of street accidents from automobiles, street cars, trucks, railway trains, etc.; the avoidance of injury from lightning and electricity; the transportation of the injured, the handling of firearms, the handling, labeling, and storing of combustibles and explosives, the management of small fires; what to do in case of fire; how to smother burning clothing; escape from suffocation in burning buildings; escape from burning buildings; poisons, their handling, labeling, and storage; avoidance of frost bite, freezing, heat exhaustion and sunstroke; avoidance, particularly by children, of exposure to injury from maddened animals; protective

measures in appropriate countries against poisonous insects, snakes, plants, and fruits.

*Emergency Treatment* — Hemorrhage from the limbs, trunk, head, nose, stomach, intestines, or urethra. Simple and compound fractures of the legs, thigh, ribs, collar bone, toes, fingers, forearm, upper arm, and skull. Sprains and dislocations of the ankle, knee, hip, sacro-iliac joint, fingers, wrist, elbow, or shoulder. Poisoning with the various common acids, alkalies, and poisonous domestic preparations. Foreign bodies in the skin (splinters), the eye, ear, nose, throat, stomach, and trachea. Burning clothing, active acid and alkali burns. Fainting, shock, epilepsy, apoplexy, hysteria, convulsions, and delirium. Pain in the head, ear, face, teeth, chest, abdomen, groin, muscles, bones, and joints. Hiccough, nausea, vomiting and diarrhea, croup, asthmatic attacks, and other sudden evidences of obstructed breathing.

*Emergency Prophylactic Treatment* — Instruction here should include, first, a discussion of the serious value of early treatment for the avoidance of later infection. This instruction should further include aseptic and antiseptic treatment, simple dressings, bandages, the cleansing of wounds, the approximation of the edges of gaping wounds, special care of superficial and deep wounds of the skin and scalp, special prophylactic treatment of powder burns and Fourth of July accidents; special treatment of other burns, special treatment of wounds of the eye, ear, nose, lips, and mouth.

**INNATE IDEA** — The rationalistic school has always attributed to thought or reason a certain inherent content of its own, irrespective of the processes of experience. It has insisted that without this original equipment experience itself would be a floating, unorganized mass of particulars, incapable of delivering any general or scientific knowledge. The particular mode in which this inherent endowment was conceived varied from time to time according to conditions. In the seventeenth century the supposed rational stock was quite com-

monly spoken of as ideas or conceptions which the individual immaterial soul brought with it to its union with the body as inborn ideas. In the interests of empiricism, Locke attacked this whole theory, contending that none of the tests relied upon by the innate school bore out their contention; that the origin of all ideas could be traced in experience itself, and that the belief in innateness, instead of being favorable to the advance of science, tended to block inquiry by consecrating as unquestionable principles any long-standing prejudice, especially if class interests were concerned in its maintenance. Locke's onslaught was substantially successful against the doctrine which he attacked. But, as Locke himself held to certain innate powers (such as comparing, combining, discerning, abstracting) of the mind, it was not difficult for the rationalistic school to regather its forces. The modified form of the conception found its classical expression in Kant, who, denying the existence of ideas, or mental contents, conceptions, beliefs, prior to sense experience, nevertheless held that the mind brought with it certain *a priori* forms and categories to the reception and organization of the materials of sense. The universal and necessary action of these *a priori* forms alone made experience capable of delivering coherent and instructive judgments. J. D.

See NERVOUS SYSTEM.

**INNS OF COURT, LONDON** — Originally these were the Hostels or Inns in which lived the apprentices, who belonged to the Guild of Law, the residence of those studying under the Masters of Law. The earliest of such Inns is said to be that of Clifford's Inn, which in 1344 was established in a demise from Lady Clifford to the lawyers of the Court of Common Pleas. Thavies Inn seems to have been established in 1348. The origin of these Inns is apparently connected with the exclusion of the clergy from practicing as lawyers in the civil courts, and the necessary consequence of training of lay lawyers. In the first instance, senior members of the guilds of law teachers and learners of law established their own voluntary classes and small residential Inns, in considerable numbers. The number of such students gradually increased, until, as Dugdale says, they divided themselves into two bodies, *e.g.* the Society of the Inner Temple and that of the Middle Temple. The Inner Temple is first mentioned in 1440 and the Middle Temple in 1442. About the year 1470, Sir John Fortescue wrote his *De Laudibus Legum Anglie*, in which he states that there were four Inns of Court, and ten

lesser Inns called Inns of Chancery, "in each of which there are an hundred students at the least, and in some of them, a far greater number, though not constantly residing. After they have made some progress here, and are more advanced in years, they are admitted into the Inns of Court, properly so-called; of these there are four in number." They were Lincoln's Inn, the Inner Temple, the Middle Temple, Gray's Inn. "In these greater Inns," Fortescue continues, "a student cannot be well maintained under eight and twenty pounds a year (£450 a year of our money), and, if he have a servant to wait on him (as for the most part they have), the expense is proportionally more . . . As to the merchants, they seldom care to lessen their stock in trade by being at such large yearly expenses. So that there is scarce to be found, throughout the kingdom, an eminent lawyer, who is not a gentleman by birth and fortune; consequently they have a greater regard for their character and honour than those who are bred in another way."

With regard to the education of the students, Fortescue gives the following interesting account. "There is both in the Inns of Court and the Inns of Chancery, a sort of Academy or Gymnasium, fit for persons of their station; where they learn singing, and all kinds of music, dancing, and such other accomplishments and diversions (which are called Revels) as are suitable to their quality, and such as are usually practiced at Court. At other times out of term, the greater part apply themselves to the study of the law. Upon festival days, and after the offices of the Church are over, they employ themselves in the study of sacred and profane history here everything which is good and virtuous is to be learned: all vice is discouraged and banished. So that knights, barons, and the greatest nobility of the kingdom often place their children in these Inns of Court, not so much to make the laws their study, much less to live by the profession (having large patrimonies of their own), but to form their manners and to preserve them from the contagion of vice. Neither at Orleans, where both the Canon and Civil Laws are professed and studied, and whither students resort from all parts, neither at Angiers, Caen, nor any other University in France (Paris excepted), are there so many students, who have passed their minority, as in our Inns of Court, where the natives only are admitted."

Fortescue devotes a chapter to answering the question why the laws of England are not (in 1470) taught in the universities, and his answer is that in the universities "the sciences are taught only in the Latin tongue, whereas the Laws of England are written, and made up of, three several languages, English, French and Latin." He mentions that the English "to this very day" speak French in their diversions

and their accounts. "In the Courts of law, they formerly used to plead in French, nor had the practice entirely fallen out, (1) by reason of certain law terms, more apt in French than in English, (2) Declarations upon Original Writs are learned and practised in French, (3) Reports of pleadings etc., in the King's Courts are digested and reported in French; (4) Many Acts of Parliament are penned in French"

The advantage of studying in the Inns of Court, as against the universities, is further emphasized by proximity to the Courts of Law, where students may hear proceedings and listen to the judges and thus become experienced in all sorts of law learning and court practice at the same time Mr C. E. A. Bedwell says it is difficult to define the status of the Inns of Chancery in their earliest days, but by the time of Fortescue the relationship of each one to the Inn of Court to which it was attached approached to that of a college to its university

The Inns of Chancery ceased to exist with the sale of Clifford's Inn in 1900 Stow says the Inns of Court were replenished with young students, graduates, and practitioners of the law, whilst the Inns of Chancery were furnished with officers, attorneys, solicitors, and clerks that follow the courts of King's Bench or Common Pleas Stow mentions that young students from the universities and some straight from grammar schools came both to the Inns of Chancery and the "houses of Court," and having spent time in studying the first elements and grounds of the law, they performed (before admittance as barristers), the "exercises" of their own houses, called "bolts" and "moots" — the course taking seven years — the same length of time as apprentices in business

Educationally, the "boltings" and "moots" are interesting, and represent to law what laboratory work is to science teaching The "boltings" were thus the "sifting" of the law with regard to cases, in which "an ancient and two barristers sit as judges, three students bring each a case, out of which the judges choose one to be argued, which done the students first argue it, and after them, the barristers" This exercise, being a private one, was regarded as inferior to the "moot," which was substantially the same kind of arguing of cases by the students to enable them to see every point of a case, but was a public exercise. The place chosen for the exercise was called the Moot-Hall. The Inns of Court appointed a bailiff of the moot, who chose the mootmen for the Inns of Chancery, and whose duty it was to "keep accounts of the performances of the exercises both there and in the house" For account of the exercises in the different Inns, see Sir Wm. Dugdale's *Origines Juridicales* (1666-1680). J. E. G. DE M.

#### INNSBRUCK, THE IMPERIAL ROYAL LEOPOLD-FRANCIS UNIVERSITY OF —

The University of Innsbruck in the Tyrolean Mountains, Austria, was established by Emperor Leopold I between 1670 and 1674, the charter dating from the year 1677 The Emperor Joseph II transformed it into a lyceum in 1782, but it was restored to university rank ten years later by Leopold II In 1810 the institution was abolished by the Bavarian government, but in 1826 it once more opened its doors under Austrian protection with faculties of law and philosophy. In 1857 a theological faculty (Catholic) was added, and twelve years later a medical faculty The university library owes its origin to a collection founded in 1745 by the Empress Maria Theresa, various collections of dissolved Jesuit colleges having been added later The attempts made in 1904 to organize in Innsbruck a faculty of law and political science, in which instruction was to be given in the Italian language, met with failure. The University had 1227 students (fifty-one women, all auditors) in the winter semester of 1909-1910, of whom 225 were auditors The largest faculty, contrary to the condition existing in all other German and Austrian universities, is that of theology (337 students), controlled by the Jesuits, which is followed by law (266), medicine (213), and philosophy (186)

**INSANITY.**—A term for a number of abnormal mental states, which are combined into complexes to make up distinct diseases. The usual statement that insanity is a mental disease or that it is an absence of sanity does not define, because we must then state what we mean by mental health or by sanity. The general term may be compared with that applied to any organ of the body, *e.g.* liver disease, heart disease, etc., and we find that the connotations of such terms are equally vague We, therefore, speak more properly of the insanities than of insanity. The variety of forms that are grouped under the general term "insanity" will be considered below.

When the varying phenomena of the insane are grouped, it is found that the differentiation of insanity from sanity is made from two points

of view: the duration of the abnormal mental conditions and the variation of the present conditions from the normal conditions of the individual. The best definition of the term is as follows: "Insanity is a disorder of the mind, due to disease of the brain, manifesting itself by a more or less prolonged departure from the individual's usual manner of thinking, feeling, and acting, and resulting in a lessened capacity for adaptation to the environment" (White). It will be seen that this definition excludes all the abnormal individuals who from birth depart from the normal in a mental way, *i.e.* all the cases of retardation, including idiocy, imbecility, and psychopathic inferiority, for their condition is continuous and not a departure from the usual manner of their thinking, feeling, and acting. On the other hand, there are excluded the temporary departures from the normal, such as slight intoxications, profound grief, fits of anger, etc. The ethical and legal aspects, so often taken as the main criteria, of knowledge of right and wrong are not considered, because these vary in the insanities as much as in normal conditions.

Perhaps of the greatest importance is the factor of the individual variation, *i.e.* the variation of the individual from his usual manner of feeling, thinking, and acting. In themselves the individual mental states may be greater or less than those of the other individuals in the environment without warranting the conclusion of "insanity." The example of the savage transported to a civilized country makes this clear. In an educated person actions similar to those of the savage are taken as signs of an insane state.

Psychologically considered, the abnormalities of the insane are only different in degree from normal mental functions. So far as the abnormal mental conditions have been analyzed, no qualitative difference from the normal has been discovered. The insanity is always a difference in the amount or the prominence of this or that mental state or states, and not a difference in the quality of the mental states. No new functions are introduced, and there are no new qualities of normal mental processes developed in the insane. Another popular misconception is that the term "insanity" is almost synonymous with the term "delusion," that all insane persons are egocentric, fantastic, abnormally excitable, or expansive. The quiet gentleman whom I meet daily has none of the latter qualities, but he is incapable of adaptation to the environment because he can perform no work that the spirits do not approve, and he is often hindered by the action of the spirits.

In civilized communities the proportion of insanity to the total population is almost a constant, 1:300. The initial symptoms are often noticed before the age of twenty, but the disturbances do not usually become sufficiently profound to warrant or to require institutional care for a number of years.

There are both physical and mental causes for the insanities. Head injuries, chronic and exhausting diseases, and various intoxications (*q.v.*) are some of the bodily causes, and on the mental side any great shock, mental stress, or worry may bring about a more or less permanent derangement of the mind. The mental factors have recently been given more prominence than hitherto, and many of the patients who were previously supposed to be insane from physical causes are now recognized as purely psychogenic cases.

The early classifications of the insanities were largely symptomatic, and can be compared directly with the classification of the fevers into hot and cold, intermittent, remittent, and continuous. On the other hand, classifications have been devised to indicate the probable causes of the conditions, and we find mentioned the insanities of childbirth, of puberty, of the climacteric, of religion, and many others. The current classifications of the insanities are either that of Kraepelin or modifications of the Kraepelinian. This author introduced into the consideration of the insanities a new conception, *viz.*, that the different forms were to be differentiated not because of the prominence of some symptom and not because the patient or his relatives assigned some cause, but because of the characteristics of the condition from the beginning to the end. In other words, Kraepelin takes into account causes, course, or development, and the final result. The following classification is a convenient one: paranoia and paranoid states, manic-depressive insanity, paresis, dementia precox, melancholia, involution, senile psychoses, infection-exhaustion psychoses, toxic psychoses, psychoneuroses, psychoses due to organic disease and injuries of brain (*qq.v.*)

The infection-exhaustion psychoses are similar to the toxic psychoses, in that confusion and delirium are usually the prominent symptoms. All of these psychoses are probably due to the presence in the blood of toxins that act upon the nervous structures in much the same way as those introduced from without, such as alcohol, opium and its derivatives, cocaine, etc. The infection-exhaustion psychoses may be divided into (*a*) infection, (*b*) delirium, (*c*) febrile delirium, (*d*) post-febrile psychoses, and (*e*) collapse psychoses. All forms have clouding of consciousness, a greater or less amount of confusion, hallucinations and delusions, and for months these symptoms may alternate with normal mental states. In the most severe states stupor is found. The senile psychoses are of little interest here, except in so far as they are associated with rather definite mental disturbances of memory. The term "second childhood" describes only some of the senile insane, and from the educational point of view these are of interest in that they enable us to make certain analyses of forgetting

and of memory loss. In many cases we find hallucinations, delusions, depressions, exaltations, and on the physical side epileptic and apoplectic attacks. Mental derangements are also sometimes found associated with brain disease or injury. These patients differ greatly in their symptoms, but all may be briefly described as "demented." The injury effects often give a means of diagnosis of the part of the brain which has been injured, and a cure is sometimes produced by appropriate surgical intervention. Aphasia is sometimes associated with these psychoses, and it often simulates a profound dementia.

Although insanity was defined as a "disorder of mind due to disease of the brain," we are still completely at a loss to correlate certain mental diseases with brain changes. In the manic-depressive psychoses, in paranoia, in dementia precox, and in the psychoneuroses no typical cerebral alterations have been found. These conditions are, therefore, sometimes called "functional" in contradistinction to the "structural" diseases, such as paresis, the senile psychoses, and the insanities due to disease and injury of the brain. In paresis the nerve cells are found to be greatly degenerated, and the cerebral cortex is found to have many abnormal elements, due to the disintegration of the cells or to the development of the non-nervous elements. The greatest changes are said to be found in the frontal and posterior association areas. In the senile insanities there is found atrophy of the brain, so that the convolutions are shrunk, and small or large areas of softening (or disintegration) are often found associated with occlusion of the arteries. The changes in the cortical cells differ from those in paresis, although both are retrograde and destructive. The pathology of the psychoses due to brain disease or injury differs in accordance with the part of the brain injured. In dementia precox changes in the structure of the cortex have been observed, but it is not certain that these are typical of the disease.

It will be noted that all the developmental defects, idiocy, imbecility, and other forms of retardation, have been omitted from the discussion of insanity. As was noted above, these are not forms of insanity, but defects or lacks of development, and are to be treated in separate articles.

**INSOMNIA** — Abnormal wakefulness or loss of sleep. The condition is the opposite of narcolepsy (*q.v.*). Insomnia may be total or partial, and may continue only one day, or for long periods. The varieties of insomnia are numerous, those most frequent being the conditions in which the individual goes to sleep at the normal time, but wakes up soon and remains sleepless the remainder of the night, and those in which the individual finds it difficult to go to sleep and lies awake for hours, tossing about until exhaustion overcomes him and sleep ensues. In both cases the amount of sleep may be normal, but the going to sleep and staying asleep are abnormal. These two kinds of insomnia are often due to bad habits of sleep, and not to any pathological nervous condition of the individual. Losses of amounts of sleep are common in many nervous and mental diseases, especially in the cases of excitements, *e.g.* in mania and in disturbed dementia precox. In the insane and in mentally normal people who suffer great pain the amount of sleep may be greatly reduced, and the patient sleep little, if at all, for several days. It is usual to find, however, that individuals complain of sleeplessness even when they have had a normal quantity of sleep, and one should hesitate to accept the individual's opinion regarding the amount and character of his sleep.

The effects of loss of sleep are much greater than those of the losses of food, and the effects are found to be mentally effective as well as physically. On the physical side there are loss of body weight, changes in the temperature of the body, and reflex nervous phenomena. A few days' loss of sleep will produce a delirium, a condition that would not follow starvation for five or six times the number of days.

On the mental side slight or continued loss of sleep is accompanied by inability to fix the attention, memory defects from inattention, and feelings of lassitude. When children exhibit these symptoms even to a mild degree, it is important to inquire regarding the amount and character of the sleep, for some cases of retardation are due to bad family surroundings that prevent the child having a sufficient amount of sleep.

Most of the cases of insomnia are due to bad habits, and must be treated as such. If the sleeplessness be due to concomitant pathological conditions of the body, the latter must be treated, and the insomnia will disappear. It should be remembered, however, that bad habits are formed here as well as for other bodily and mental activities, and it is not uncommon to find that the habit of sleeplessness is formed by only a few days' illness. Sleeplessness may also be due to imaginary causes, and it is most easy to produce a sleepless night by calling the attention of one who has taken coffee to the fact that this beverage is a stimulant and will produce wakefulness. On the other

**INSISTENT IDEAS.** — See FIXED IDEAS.

hand, it is equally easy at times to produce sleepiness by calling attention to monotonous sounds and by recommending innocuous drug-like prescriptions. S. I. F.

**INSPECTION OF SCHOOLS.** — Some system of school control through inspection has always existed, since the time when education was in the hands of the Church and teachers were licensed by the *scholasticus* or the chancellor, to the modern period when the State has taken over the charge and maintenance of schools. For the medieval period see BISHOPS' SCHOOLS; CHURCH SCHOOLS, CHANCELLOR, SCHOLASTICUS, VISITATIONS. During the Reformation period immediate inspection and visitation of schools was exercised by the local pastor, and consisted usually in an examination of pupils and teachers. The earliest system of state inspection was probably introduced at Gotha (*q v*) under Ernest the Pious (*q r*). Inspection by official inspectors of the State was introduced on a large scale when the State began to supply funds for the maintenance of schools. Thus in England the first government inspectors were appointed in 1839, when a grant was made in aid of school buildings. Inspectors who visited Church of England schools had to be approved by the Archbishop. The first instructions were issued in 1840, and required the inspectors to report on the number of schools in their districts and the state of education there, to inspect aided schools, and to recommend the appointment of teachers. These remained essentially the duties of inspectors for many years. After 1861, when payment by results was introduced into elementary education, the inspectors began to examine the pupils, and this system left its mark on English inspection. The large majority of inspectors were professionally untrained, although from 1879 a number of schoolmasters were appointed as assistant inspectors. Administrative duties, such as the examination of registers, time-table, and log-books, continued. The broader function of supervising instruction and the teaching process, and in this way assisting the teachers, is only gradually being recognized as of primary importance. No special professional qualifications are yet demanded from those who are appointed to inspectorships, as long ago as 1879 Mr Rathbone moved in the House of Commons that "before being appointed to an independent post, newly appointed inspectors should have one year's training under an experienced in-

spector, unless they have previously been engaged in the education of children for a sufficient time to make this unnecessary." The great need of the present, however, is a requirement of professional training and experience as a necessary qualification for appointment, if the inspecting staff is to secure the confidence and professional support of teachers. Special inspectors are also employed for art, domestic subjects, drawing and handicrafts, rural education and agriculture, music, and the training of teachers. The employment of local inspectors, in most cases teachers of experience, by local authorities is increasing rapidly. Since 1899 the Board of Education has undertaken to inspect secondary schools on request, while all schools which desire to qualify for the state grant must submit to an inspection of both instruction and premises.

**INSPECTORS, STATE.** — See SUPERVISORS, HIGH SCHOOLS, STATE SYSTEMS OF.

**INSTINCT** — **Use of Term** — Modern writers have not agreed upon a fixed meaning of the term "instinct." The field of instinct is the common ground of both psychologists and biologists. The experimental biologists take an objective viewpoint with respect to instinct. For them, instinct is a combination of congenital responses, unfolding themselves serially under appropriate stimulation: the series as a whole being generally but not necessarily adaptive in character (always so from a Darwinian standpoint). Each unit reaction or element in this series may be looked upon as a "reflex." An instinct is thus a concatenated series of reflexes. Such a series of reflexes, or an instinct, is illustrated by the first attempts at nest building of young birds, by the first fighting responses in young animals of any kind, and by the capturing, killing, and eating of prey (as appears in kittens), etc. The combination must be observed on its first appearance if it is to be seen "pure," i.e. without the presence of the habit-factor.

**Reflex** — If this definition of instinct is to be acceptable to the animal psychologists, it is necessary to add that the term "reflex" (including tropisms under this head) should not be understood to mean an absolutely fixed and unalterable type of response. Jennings, Mast, Yerkes, and many other American writers have shown that the responses even of the pro-

tozoa and of the lower metazoa are not reflex in the sense of being fixed and stereotyped. Two factors determine the overt observable response: the extra-organic stimulation (sensory stimulus) and the intra-organic processes (physiological states). If either set changes, the overt response changes, either greatly or little; *e.g.* the stentor may react in several different ways or in the same way, but more or less intensely, to the same (extra-organic) stimulus, provided the physiological state of the animal be different at different moments of stimulation. Yerkes has shown that the amount of the reflex movement of the leg of the frog called forth by an electric stimulus can be greatly increased by introducing an auditory stimulus simultaneously with the electric stimulus, although the auditory stimulus calls forth no visible response when given alone. As the interval between the auditory and the tactual is gradually increased, the reinforcement of the reflex response gradually decreases, and finally gives place to an actual inhibition. Similar conditions hold in the case of the human knee jerk and other reflex-like phenomena.

In general terms, then, while the reflex is the simplest type of organic response, calling on the structural side for the presence merely of an open pathway from receptor to effector (or from sensory surface to muscular mass when the nervous system is lacking), at the same time many influences, as has been well brought out by Sherrington, are at work, or may be at work, to alter the perviousness of this pathway (blockage on the reverse at the synapses, momentary or more lasting differences in tonicity of the musculature, etc.), and thus to alter the intensity, and to some extent, even the character of the so-called "simple reflex" responses. "Simple reflex," then, is a mere concept — a general term to cover segmental reactions which appear at first sight to be relatively simple in character. If the individual units composing the series of responses which are grouped together to give us the total picture of an instinct in action are variable in their function, then the series as a whole must necessarily offer still greater possibilities of variation. If the above contention for the variable character of the simple reflex is granted, the biological or objective definition of instinct is acceptable.

**Presence of Consciousness** — The older psychologists, the early naturalists, and the metaphysicians have complicated the discussion of instinct by bringing in the question as to whether consciousness is present, and if so, to what extent. This additional element of consciousness in the instinctive response was supposed to differentiate instinct from reflex. However interesting a question this may be from the standpoint of general psychological theory, it seems relatively futile to attempt to introduce psychological considerations of a structural kind into any discussion of instincts

in the present state of animal psychology. If instincts are defined as above, it is clear that neither the human animal nor one lower in the scale is conscious of the end to be gained by the first exercise of any instinctive group of responses. Even the human adult cannot image what has never formed a part of his perception. It is unreasonable to suppose that there can be any plan, picture, or image of a nest of any kind in the mind of the thrush which has been hatched in an incubator and reared in isolation from all other birds; nevertheless, at the proper time she will construct her nest true to the species type, and go through with the whole breeding cycle. The separate movements from a psychological standpoint are not voluntarily initiated; there are no images anticipatory of the series of acts or of their results. As James states it, the animal is so constructed that it must act in that way, in the presence of such stimuli. On the other hand, it may be argued with some justice that the process may be and probably is an intensely conscious one from the standpoint of the presence of sensations, one has good reasons for supposing that the bird is visually aware of the stick and the twine — of their form, size, and color (though even these functions are really hypothetical until decisive experiments have been made), — and that she is conscious of her movements toward them, of their weight and contact values as she picks them up, and, furthermore, that she is vividly conscious of her own emotional state. It may be likewise argued that after the bird has built her first nest, arguing by analogy from human processes, she might be able to image it when absent from it, since by building it instinctively she has laid a perceptive basis for the rise of an image. In other words, while the animal is not planning or controlling the situation voluntarily in this first exercise of the instinct, she is "feeling" vividly her emotional state and is conscious, however poorly she may analyze the experience, of the visual, auditory, tactual, and kinesthetic stimuli which assail her from within and without as she successively goes through with the separate acts.

**Method of studying Instincts** — Present-day comparative psychology, looking at instincts from the above objective standpoint, is taking up individual instincts and making a detailed experimental study of them. It is thus rapidly enlarging and making more definite our concept of what in any given case is an instinct. It is showing that what was earlier called instinct is in most cases a delicate and complex combination of instinct and habit. It is impossible except by laboratory methods to separate the congenital (phylogenetic) from the acquired or habit form of reaction (ontogenetic). Within the last few years it has been shown that the responses of practically every organism, from amoeba to man, are plastic and modifiable, and that all animal forms actually do alter their

original or primary congenital modes of response, where necessary, in the direction of habit. The young of any given species must be watched from the moment of birth until the last instinctive cycle (those connected with reproduction) appear. This has now been partially done, but only in a general way, for the young of several species of birds and mammals. The work of Morgan, Spalding, Porter, Watson, Craig on the birds, and of Wesley, Mills, Small, and Yerkes on young mammals, shows quite clearly that many apparently simple instincts are not completely congenital at all. Lloyd Morgan has shown that the drinking response in young chicks is very imperfect until habit factors enter in. Breed, at Harvard, has shown that the pecking response in the same animal is very imperfect at birth, and that it is only gradually learned.

Many of the instincts at birth, however, appear, though later experiments may prove the case to be otherwise, perfect without modification, such as the building of the first nest by young birds, brooding, rearing of the young, many of the responses of the insecta, etc. Unquestionably, as these activities are engaged in from season to season, habit factors may and do enter in. The scientific way, then, of approaching the problem of instinct is to isolate the young animals, and to observe what reactions will from time to time unfold themselves (congenital responses), and then to determine experimentally how these congenital responses are supplemented and changed by habit.

The explanation of why there is a congenital response taking place before experience or tuition can have played any part must be sought for on evolutionary grounds. All organisms are born into the world with certain structural modifications which force the animal to react, however imperfectly, in a certain way in the presence of certain stimuli. The origin of such structures is a mooted question to-day, and no satisfactory answer can be given. We sketch below the two most important hypotheses.

**Origin of Instincts.** — Darwin's theory of the origin of instincts by the process of gradually heaping up favorable fluctuating variations, the process as a whole being under the influence of natural selection, has already been discussed (See DARWIN.) In recent years Darwin's theory has been shown to be untenable. In the first place, while it is true that all individuals of a given species do show fluctuating variations when compared with the norm or average, it has been shown by a number of investigators, including Nilsson, De Vries, Jennings, Morgan, Pearl, and others that such variation cannot be heaped up along specialized lines, as Darwin supposed. Fluctuating variations are not inherited; consequently, they have no bearing on the theory of evolution.

"The use-and-disuse hypothesis" (and the

theory of lapsed intelligence of Wundt, Cope, and others, based on it) of Lamarck, and espoused as a supplementary hypothesis by Darwin, has been practically abandoned by biologists for lack of experimental support. The same may be said of the third of Darwin's principles for accounting for the origin of instincts, namely, his theory of secondary sexual characters. Being forced to abandon these Darwinian hypotheses, we are forced by the experimental method to seek some other mode of accounting for structural differentiations. Fortunately, the recent work of Bateson, De Vries, Nilsson, McDougall, Vail, and Shull, and of Tower and others, throws light on this question. De Vries's work on the evening primrose, *Oenothera lamarckiana*, is probably best known. For over twenty years De Vries bred this plant under conditions of scientific accuracy. His first culture gave a wholly new mutation — *i.e.* a wide and totally unexpected and unpredictable variation, as distinct from the usual slight, fluctuating variations. In the continued cultivation of it other mutations — some of which are very striking, such as the dwarf, *O. Nanella*, and the giant, *O. Gigas* were observed. Some twelve mutations from the original pure strain, *O. Lamarckiana*, have been described by De Vries, all of them breeding true to the type, and appearing without intermediate forms. In other words, differentiation in this plant takes place by jumps — mutations, and such mutations are hereditary. McDougall, Vail, and Shull have shown that these mutations may be experimentally produced by the injection of certain solutions directly into the plant ovaries.

By far the larger amount of this work on the production of new types and races has been done on plants. The color form and behavior changes noted by Tower in his chrysomelid beetles parallel the work of De Vries on plants. A great mass of work, similar in character to that of Tower, is accumulating. In addition to mutations which have been obtained experimentally, it is now generally recognized as being the most probable assumption that the breed of hornless cattle in Paraguay, the long-horned sheep in Brazil, the Ancon sheep in Massachusetts, to use familiar illustrations, arose suddenly and by mutation. De War and Finn in a recent book, *The Making of Species*, devote several pages to a discussion of mutation in animals.

The conception that the special structures underlying instinctive responses arise by discrete and sometimes large variations, as well as that species themselves arise in this way, is rapidly gaining ground. According to the mutation theory, congenital adaptations are not slowly produced by environment, but are the accidental correlates of the particular structures with which the mutant happens to be endowed; and it is with these adaptations that the new type must begin its struggle for

a suitable environment. If the mutant springs forth at a time when the environment is such that the actions on the part of the animal necessary for obtaining food, shelter, and the reproduction of its kind can be called forth, — or, put the other way around, if the mutant is fortunate enough to begin life with a series of responses adequate to meet environmental demands, that type of mutant can exist and procreate its kind, leaving adequate paleontological record behind it, if not, the variant is annihilated, without leaving marks of its temporary existence. Natural selection, while not being responsible for the formation of new structures, and hence of new responses, is still operative in eliminating the unfit variants. What boots it whether the snail is coiled to the right or to the left; or that certain crustacea have one claw so much overdeveloped that its possession must be a disadvantage, so long as these animals possess enough favoring adaptations to make the necessities of life obtainable? Selection will allow the mutant many peculiar and non-advantageous structures, it steps in only when there is an actual deficiency in the number and complexity of functions necessary for life and reproduction.

Human psychology is especially interested in this theory of mutations by reason of the fact that it does away with the necessity of looking for adaptive value in certain emotional and instinctive attitudes, as in dizziness, trembling, nausea, and many other such reactions which put the human subject at a disadvantage in critical situations.

**Important Human and Animal Instincts** — Any complete or general inventory of animal instincts is impossible at the present time, because (1) animals possess so many instincts that students of behavior have not had time to study them exhaustively in any one species, and (2) instincts differ too widely in the different species. All animals may be said roughly to possess many adaptive specialized congenital modes of reacting to food, enemies, shelter, and sex, and to possess, in addition, many other congenital modes of response which are accidental and non-adaptive. Special studies in animal psychology will give soon, it is hoped, a clear and concise knowledge of the order of appearance and the number of instincts in any given form, their fixity, variability, and modifiability, their constant, cyclic or deferred character, etc.

The important human instincts appearing later than the group immediately connected with the preservation of life (such as sucking, crying, sneezing, etc.) are in just as much need of careful study as are the instincts of animals. Angell in his *Psychology* gives the following as the probable list: Fear, anger, shyness, curiosity, affection, sexual love, jealousy, envy, rivalry; sociability, sympathy, modesty (?), play, imitation, constructiveness, secretiveness, and acquisitiveness. It is easy to see

first that many of these are questionable instincts, as for example, modesty, imitation, affection, secondly, that many of these are general terms which cover groups of instincts. Play, for example, consists in the releasing of many congenital responses, and the number and character of these responses differ widely with respect to the objects calling them forth. A kitten will play with its tail or a ball of twine, or it will engage in a mock combat with its fellow, or tease a helpless mouse. The responses differ greatly in the several cases. A similar condition obtains in the child. Thirdly, many of them are so masked by the network of habits which the child has formed before the responses appear that the pure and characteristic instinctive group cannot be isolated. Jealousy, envy, rivalry, sociability, and sympathy are of this type. In the child they show really the beginnings of conscious attitudes. There is an instinctive *Anlage*, but little more. The works of Preyer, Perez, Shinn, Major, Baldwin, and Stern deal largely with instincts in the child, but mainly from an observational standpoint.

**Psychological Bearing of Instinct** — While the mechanics of instinct *per se* interests the student of behavior mainly, the human psychologist is concerned with them first because of the light they throw on the origin of emotion, emotion always appears in the human being in conjunction with instinctive expression. Secondly, by reason of the fact that all volitional control has its origin in instinctive movement. Thirdly, by reason of their intimate bearing on adult impulses, motives, and attitudes.

**Pedagogical Bearing of Instincts.** — A study of instincts is of the highest importance pedagogically because the changes in the interests of the child are somewhat determined by changes in the instinctive and emotional complexes. Instincts ripen serially and decline serially — each one as it comes brings about an interest in a different set of objects and a different focus of attention, as shown very clearly at the onset of puberty. James, in his *Principles of Psychology*, speaks very vividly of "striking while the iron is hot," i.e. of choosing the favorable moment when the child is instinctively interested in a group of objects, to instill proper modes of reacting to these objects and to store up knowledge about them. While he largely overestimates the number, independence, and permanence of instincts of this class in man and of their adaptability for such a stamping-in process, there is such an element of truth in what he says that no teacher can neglect the study of human instincts.

A large group of educational psychologists, in their adherence to the reduplication theory of Cope, have carried the process just described to an unwarranted extreme. The child is supposed to duplicate in ontogeny the whole phylogenetic process. We are taught by them to find in the growing child a series of culture

## INSTITUTE

epochs, similar to the rough-stone age, the hunting stage, and the agricultural stage in primitive man. The above school has based educational theory and practice on this hypothesis. It remains to be said that this aspect of the reduplication theory is based on the most flimsy biological speculation, and that modern experimental biology finds few data supporting it. In exceptional and isolated cases there appear to be certain growth processes which are apparently reduplicative in character. But nearly all such changes take place in the embryonic stages or during the early period of infancy. To carry this process over to the child of eight, ten, and twelve years of age, and to base an educational system upon it, is building upon a foundation of sand.

### INSTITUTE, FRENCH (INSTITUT DE FRANCE)

— A French association comprising a group of societies for the advancement of literature and science in all their branches. An association of this type had been planned by Richelieu when the French Academy was established in 1635. In the same century, under the influence of Louis XIV and some of his ministers, there sprang up the Academy of Fine Arts (1648), the Academy of Inscriptions (1663), and the Academy of Sciences (1666). These were all abolished by the Convention in 1793, and in their place the *Institut National des Sciences et des Arts* was established in 1795, "charged with collecting discoveries and with perfecting the arts and sciences." Its members were now drawn not from Paris alone, but from all parts of France, and foreign associates were also elected. The plan appears to have been suggested by Talleyrand and Condorcet. There were three classes devoted to (1) physical sciences and mathematics, (2) moral and political sciences, and (3) literature and fine arts. In 1803 the Institute was reorganized with four classes with a new distribution, excluding moral and political sciences at the order of Napoleon. In 1816 the old names of the academies were restored, and in 1832 the Academy of Moral and Political Sciences was revived and the name was changed to *Institut de France*. The membership consists of regular and honorary members, foreign associates, and corresponding

## INSTITUTES

members. Election is by ballot, confirmed by the government. The members receive 1500 francs a year each. The Institute is located in the old Mazarin Palace. The library, which includes the old town library of Paris allotted to it in 1797, contains a valuable collection of books. The Institute has the right to nominate professors to the College of France, the Museum, Schools of Rome and Athens, School of Maps, School of Oriental Languages, Conservatory of Arts and Handicrafts, the Observatory and the *École Polytechnique*. One of the important functions exercised by the Institute is the award of prizes for distinguished services to literature, science, and arts. Funds are provided by the state and private benefactions, the general funds being administered under the supervision of the Minister of Public Instruction, and departmental funds by each academy.

See ACADEMY.

**INSTITUTES** — The teachers' institute is a distinctly American institution. As originally organized, the purpose of the institute was to provide opportunities for the review of the subjects taught in the common schools, to give suggestions on methods of teaching and school management, and to stimulate teachers to self-improvement. For a time the institute did the work of the normal school in the professional training of teachers, and in parts of the country, where normal schools do not meet the needs of rural communities, the institute continues to provide abbreviated courses of professional training. Where, however, normal schools are reasonably well organized, the institute serves the purpose of an education gathering for the discussion of broader professional subjects. The summer school, in many parts of the United States, is taking over the function of the teachers' institute.

In some parts of the country the institutes are under state auspices and are generally organized by the state superintendent of public instruction. In most states the county is the unit, and the county superintendent is the responsible director. In cities of 20,000 and more inhabitants, separate institutes are generally held under the direction of the city superintendent of public schools. In most of the states there are special appropriations from the school funds that meet part of the cost of the institutes. Such funds are generally supplemented by membership fees on the part of the teachers or by fees that accrue from the licensing of teachers. The duration of the institute varies from one day to six weeks. Some states have paid corps of institute in-

structors, but most states secure the services of members of the faculties of the state normal schools and colleges and other educational workers to give the instruction. In institutes that are in session a week or less, the instruction is generally of a purely professional character and is given in the form of lectures. Where the sessions are of longer duration, the teachers are organized into classes for more definite academic instruction in the elementary school studies.

**Historical Development** — The first teachers' institute was held at Hartford in the autumn of 1839 by Henry Barnard (*qv*). Twenty-six young men, some of whom had already taught in the common schools, were organized into a class and given instruction for six weeks. In the previous winter Barnard had asked the state legislature to make an appropriation to enable him to organize two such institutes, one for male and one for women teachers. As the measure failed in the senate, he organized a class of men at his own expense, with slight aid from some friends of education in Hartford. He wished to show the people of Connecticut, he said, "the practicability of making some provision for the better qualification of common school teachers, by giving them the opportunity to review and extend their knowledge of the studies usually pursued in the district schools and the best methods of school management, instruction, and government, by means of recitations and lectures conducted by experienced and well-known teachers and educators."

At this first institute held at Hartford, Charles Davies, (*qv*), the well-known author of mathematical textbooks, gave instruction in arithmetic, Thomas H. Gallaudet (*qv*), had the classes in composition and school government, Mr. Barton, of the teachers' seminary at Andover, gave lessons in reading, Mr. Brace and Mr. Wright, of the Hartford schools, had charge of the subjects of geography, spelling, and writing, and Mr. Barnard himself gave lessons in principles of teaching and school hygiene. "A portion of each day," writes Mr. Barnard, "was devoted to oral discussions and written essays on subjects connected with teaching. The students also spent some time in visiting the best schools in Hartford."

The experiment was repeated the next year (1840), with the addition of a class for women teachers. It was not until 1847 that the legislature of Connecticut provided the funds for the organization of institutes (two in each county) at state expense. Private initiative, however, had made possible many such institutes in different parts of the state, at which such well-known educators as Henry Barnard, Thomas H. Gallaudet, William A. Alcott, Jesse Olney, Charles Davies, and J. E. Lovell gave instruction. These early gatherings in Connecticut were not called institutes, but teachers' classes.

In 1842 J. S. Denman, the superintendent of schools in Thompsons County, New York, conducted for two weeks a class of teachers for the purpose of "reviewing and extending the topics taught in the common schools." He called his class a teachers' institute. This was probably the first use of the term. In the following year Mr. Denman held an institute for six weeks. He was assisted in the instruction in his institutes by James B. Thomson, David Powell, Salem Town, and David P. Page (*qqv*). By 1844, remarks Mr. Fowle in an article published at that time, institutes were held in most parts of the state. In 1847 the legislature of New York appropriated \$60 toward defraying the expenses of teachers' institutes in each county in the state.

Rhode Island was probably the first state to organize institutes under state auspices. Henry Barnard, then at the head of the school system, held institutes at Westerly and Providence in 1844. During the next few years institutes were held in all parts of the state, and such well-known educators as William H. Wells, John Kingsbury, Charles Davies, Josiah Holbrook, Samuel S. Greene, Francis Wayland, and William B. Fowle (*qqv*), were secured as instructors. The institutes of Rhode Island had several unique features. One of these was the teaching of "model lessons" by William G. Baker. A covered wagon was fitted up, and this conveyed Mr. Baker and a dozen children about the state. At each institute Mr. Baker gave lessons in the different elementary school subjects, to show the members of the institute "how to teach." Another feature was the distribution of educational tracts and almanacs at the evening sessions, which were of a general nature and attended by the people of the community.

An institute was held at Sandusky, Ohio, in 1844, under the guidance of Judge Ebenezer Lane. He was assisted by Henry Barnard, Salem Town, and A. D. Lord. Many similar meetings were held during 1845 and 1846, that were supported by private contributions, but in 1847 the state legislature authorized the county commissioners to appropriate certain funds for the payment of instructors and lecturers at teachers' institutes.

As Massachusetts had organized two state normal schools in 1839 (Framingham and Westfield) and a third in 1840 (Bridgewater), institutes were not held in that commonwealth until 1845. In October of that year, Horace Mann (*qv*) organized a ten-day institute at Pittsfield, and before the end of the year institutes were held at Fitchburg and Plymouth. Massachusetts secured from the first a corps of strong men to give the instruction at the teachers' institutes, including such distinguished educators as William Russell, John Pierpont, Sanborn Tenney, Samuel S. Greene, Lowell Mason, C. D. Colburn, Josiah Holbrook, William H. Wells, and at a later date the

## INSTITUTES

three Swiss-Americans, Louis Agassiz, Arnold Guyot, and Hermann Krusi, Jr (*qq v*). As the instructors were employed by the state board of education, they were also assigned to the different normal schools to give courses of lectures and lessons. It may also be mentioned that in Massachusetts such new subjects as singing, physiology, and mental arithmetic were popularized at the institutes before being introduced into the schools.

The first teachers' institute was held in Pennsylvania at Columbus, Warren County, in 1848. It was conducted by Fordyce A. Allen (*qq v*) and J. C. Moses. Institutes were held in Lawrence County in 1851, Indiana County in 1852, and Lancaster County in 1853. In 1854 the legislature granted aid to teachers' institutes, and in 1867 they were made an integral part of the Pennsylvania school system. Among those who took active part in the early institutes held in the Quaker State were Thomas H. Burrowes, James P. Wickersham, Fordyce A. Allen, John F. Stoddard, and S. S. Halde-man (*qq v*).

With the organization of the state school systems, teachers' institutes in one form or another became a part of the educational machinery, and although they have changed greatly in character in the more thickly populated states, they are still a part of the school systems of practically all the American states. Originally peripatetic normal schools, often extending their sessions into weeks, to-day in such populous states as Massachusetts, Rhode Island, Connecticut, and New Jersey, they are rarely in session more than one day. At an earlier period the institutes were of special value in arousing and solidifying public sentiment in favor of state-supported schools, in disseminating useful knowledge concerning methods and principles of teaching, and in enriching the common school course by popularizing new subjects. As the number of trained teachers has increased, the institutes have tended more and more to become general education conventions for the discussion of current educational problems. W. S. M.

**Present Status.**—As at present conducted, the teachers' institutes aim to provide general academic instruction, professional training, discussion of immediate problems, and professional inspiration. They thus attempt to take the place of training schools, teachers' associations, and social organizations. As a rule institutes are held once a year and last five days, though they vary from one day, in New England, to five or six weeks in some of the Southern states. The most common unit is the county, except in Colorado and Nevada (institute districts), and New York (school commissioner districts). In Rhode Island a state institute is held. Counties may join to hold institutes. In three states (Michigan, Nevada, and Nebraska), state institutes are held. Attendance is compulsory in twenty-eight states, and, although

## INSTITUTES OF INSTRUCTION

optional elsewhere, various inducements (*e.g.* continued salary, per diem expenses, mileage allowances, and a percentage toward grading) are offered. The institutes are maintained by the state or by fees from teachers for examinations, licenses, and registration. Instructors may be appointed by the state or by the local authority from a list prepared by the State, in some states the instructors must be licensed. Commonly the normal school faculties supply instructors, although the range and scope is, of course, much wider. The institutes are in the main attended by rural school teachers, occasionally by city school teachers, hardly ever by high school teachers. The system of institutes has been severely criticized within recent years. The chief ground of objection is that it is an anachronism. It had a place when there were no facilities for the training of teachers. But since the establishment of normal and summer schools it merely connives at inadequately trained teachers in attempting to do training work for about five days in a year. Further, the programs are as a rule haphazard, unconnected, and require no preparation, and are followed by no discussion. Frequently the lectures have become inspirational and entertaining in the worst sense. The tendency at present is to permit teachers to attend summer schools in place of institutes, to lengthen the period of the institute, making it almost a summer school, to require definite preparation of some connected educational topics, and to conduct the meetings as classes in a school or college. Ultimately the institute will disappear, but before that time professional standards must be raised, universal training and higher qualifications must be insisted upon, and teachers' associations must play a more significant part in the teacher's life than at present.

**INSTRUCTION PERIOD.** — The weekly program of the school is made up of periods which are assigned in varying quantity to the several school subjects, hence we speak of the arithmetic period or the grammar period. These class periods are further classified according to the function, use, or value of the activity employed. Thus, if the period is assigned for the purpose of instruction by the teacher, it is called an instruction or recitation period, if for preparation by the pupil, a study period. All periods cannot be thus classified, as several purposes may be present in one exercise. H. S.

**INSUBORDINATION** — See SCHOOL MANAGEMENT, REWARDS AND PUNISHMENTS

**INSURANCE COMPANIES, EDUCATIONAL WORK OF.** — Quite recently insurance companies have realized that in addition to guarding the interests of policyholders by thorough medical inquiry, it may be possible to lower the death rates generally by a system of education along the lines of sanitation and hygiene. It is recognized to-day that many diseases are preventable, and that, if the population generally could be educated regarding the possibilities of prevention, the population mortality might be effectively reduced. It is for this reason that certain life insurance companies are working hand in hand with public officials in the direction of spreading the gospel of education in sanitary and hygienic matters. The general subject of prevention of disease and conservation of human life has been fully dwelt upon in the report of the National Conservation Commission by Professor Irving Fisher, entitled, *National Vitality, its Waste and Conservation*.

The large majority of life insurance companies conduct so-called "ordinary" business. The risks on which they write policies belong to a better financial stratum of society, and are able to take insurance in amounts of \$1000 and upwards. The mortality in this group, for obvious reasons, is lower than in the general population, and at some ages is only one half of the mortality in what may be termed "industrial" population. A number of the companies not only write so-called ordinary insurance, but industrial insurance as well. This form of insurance has been arranged for the working

classes, and permits them, through the payment of small weekly premiums, to insure themselves against death. For this group, however, it has been necessary to devise a special mortality table based on the experience gained from a study of the mortality in this particular group. The individuals comprising the industrial masses are less in a position to avail themselves of the opportunities to guard themselves against disease, and for this reason a campaign of education directed specifically to them may have a tendency to bring about better results than a campaign among the better circumstanced.

Of the companies which have attempted a campaign to improve the physical conditions and the health of their policyholders, probably the most noteworthy are the Provident Savings Life Assurance Society, recently merged with the Postal Life Insurance Company, the Metropolitan Life Insurance Company, and the Equitable Life Assurance Society. The first named company, in August, 1909, organized a so-called "Policyholders' Health Bureau," through which the company has issued health bulletins to policyholders, keeping them informed of the most recent advances of science in the promotion of health and the prevention of disease, and answering inquiries on matters of health. The various bulletins which have been issued by the company treat of the evil results due to intemperance, and overeating, and the contingencies from various poisons. In one number, the bureau discussed certain of the so-called preventive diseases, such as pneumonia and typhoid fever. Another number was given over to the use of narcotics and the dangers attending their use.

Outside of the field of the life insurance companies several of the accident companies have published bulletins in reference to the prevention of accidents. Here in particular may be mentioned the bulletin published by the Fidelity and Casualty Company of New York on *The Prevention of Industrial Accidents*.

The campaign of education which was begun in 1909 by the Metropolitan Life Insurance Company of New York has been directed primarily to its so-called industrial policyholders, representing all nationalities, and in many instances individuals who have but little education and no opportunity of coming in contact with modern current thought on the subjects of health and hygiene. To meet the needs of this large group, the company through its agents who visit the policyholders weekly has distributed pamphlets of various kinds on the movements which have sprung up to improve living conditions and to prevent disease. For years the company has published a periodical. Incidentally, it has attempted to place in the hands of its policyholders articles written in a popular fashion on subjects dealing with the health of the family, and in particular with the health of the children in the family. The magazine in a sense is a children's magazine.

The illustrations which it contains, and many of the articles especially prepared for it, have been published with the children in mind. Some of the articles which have appeared in the last year are the following. *Just Flies*, calling attention to the danger of the fly as a transmitter of disease; *If you have a Baby, Place this where you will See it Every Day*, *Chinese Doctors*; *Daily Health Hints*, *Summer Clothing for the Children*; *Our Glorious Fourth*; *Seven Laws of Infant Health*; *Physical Defects which may be Overcome*, etc.

The company, as would be expected, suffers a heavy loss from deaths due to tuberculosis. In the year 1908 there was a total of 92,411 deaths, of which 16,585 were caused by tuberculosis. Of these the number of deaths of children over one and under fourteen years of age was 1330, or 8.01 per cent, and it is clear that the reduction of mortality from this dread disease is of vital importance to the company. An effort has been made to educate policyholders regarding the causes of the disease, its cure, and its prevention. Over four and a half million copies of a pamphlet, *A War upon Consumption*, printed in ten languages, have been distributed to policyholders. This pamphlet, as well as others which are issued by the company, was put in an attractive form so that it would be read. Copies have been distributed to school children in certain cities at the request of the authorities, and in one instance the pamphlet has been used as the text for compositions and essays written by the children. Supplementing the above pamphlet, the company prepared a list of the tuberculosis sanatoria, hospitals, dispensaries, classes, and associations in the United States and Canada, which it has distributed among its policyholders suffering from the white plague, and one which is entitled, *Directions for Living and Sleeping in the Open Air*. It is hoped through this pamphlet many policyholders who are unable to obtain sanatorium treatment may attempt to obtain treatment in their own homes. The company has at present in preparation a booklet on domestic hygiene and the care of children.

The company has also been experimenting for the last two years in the direction of sending visiting nurses to its industrial policyholders suffering, not only from tuberculosis, but from any disease which may require nursing. But the actual treatment and care given by the nurse is probably the least of her activities. From the standpoint of prevention, the value of the nurse consists in the education along sanitary and hygienic lines which she is spreading broadcast in every home which she visits. There can be little doubt that in time, while it may not be possible to prove the matter by actual statistics, there should be an improvement to a greater or lesser extent in the mortality of policyholders, and in particular their general welfare will be materially en-

hanced. It is hoped that the nurse will be of particular value in preaching the doctrine of the prevention and cure of tuberculosis in connection with the pamphlet, *Directions for Living and Sleeping in the Open Air*, to policyholders unable to obtain sanatorium treatment. A nurse, plus the pamphlet, should in time produce tangible and visible results. Maternity cases have been given particular consideration in this nursing experiment both before and after the birth of the child.

As a matter of interest, it may be mentioned that at present the experiment is being conducted in approximately 775 cities and towns, in the greater number of which the service has been installed but a very short time. The statistics for the year 1911 show a total of over 675,000 visits. Visits are requested in the main for acute diseases, that is, where there is a stronger possibility of recovery. Under these may be included pneumonia, grippe, bronchitis, and various children's ailments such as convulsions, paralysis, etc.

It may be said that an insurance company that protects the lives of the working classes has assumed very definite responsibilities. To what extent such a company may further enlarge or increase its activities is problematic. The activities mentioned above indicate the possibilities, at any rate. Much will depend on the extent to which it may go under the provisions of its charter and the laws of the several states. That the extension of such work by an insurance company, that the endeavor on its part to better the circumstances of its policyholders and in particular to increase the length of their lives, are subjects worthy of the deepest consideration, is beyond doubt.

**INTEGRAL CALCULUS** — See CALCULUS

**INTEGRATION OF STUDIES.** — See CORRELATION

**INTELLECT.** — Intellect is a term which has been employed in a broad and in a narrow sense. In its broadest sense it includes all of the processes of knowledge as distinguished from the emotions and will. Thus we speak of the exercise of the intellect on the part of any "one who is of higher grade than the imbecile." In the narrow sense, the term intellect has been employed to designate the higher forms of mental activity as distinguished from certain of the lower forms of knowledge. Thus the mere processes of sensory experience are not to be regarded as belonging under this term when used in its narrower sense. This distinction is clearly marked in the title employed by one of the great English psychologists, Bain, in his volume *Senses and Intellect*. Here the intellectual processes are those of discrimination, comparison, memory, judgment, reasoning, etc. The processes of

## INTELLECTUAL EDUCATION

sense recognition, on the other hand, are treated as forms of knowing which are carried on at a lower level. This distinction is very often employed in defining the relation between human and animal consciousness. Man is said to be distinguished from the animals by his possession of intellect. This, of course, does not signify that man is superior to the animals in sensory processes. It indicates rather that the material which is supplied by the senses is employed in human life in higher forms of comparison and discrimination.

**INTELLECTUAL EDUCATION.** — See EDUCATION

**INTELLIGENCE TESTS, BINET.** — See TESTS, INTELLIGENCE.

**INTEMPERANCE.** — See TEMPERANCE, INSTRUCTION IN; ALCOHOL, THE USE AND PSYCHOLOGICAL EFFECT OF.

**INTENSITY** — One of the attributes of sensation. The intensity of the sensation is related to the amount of energy that affects the sense organ. The difficulty in dealing with the intensity of mental states is that it is impossible to compare two intensities unless they are in consciousness in close succession, and then it is not possible to do more than say that one intensity is greater or less than another. Measurement in the sense that it is used in the physical sciences is impossible. The only measurements that have been made are of the amount of physical stimulus that will just give rise to a sensation in any department and the difference in two physical intensities that may just be appreciated. The discussion of the first problem is given under the different senses, of the second under Weber's Law. W. B. P.

**INTERACTION** — See BODY AND MIND; NERVOUS SYSTEM

**INTEREST** — The "doctrine of interest" in education is a sort of shorthand expression for a number of different motives, which focus in the recognition of the necessity of discovering points of genuine and intimate contact between the subject matter of instruction and the vital experience of pupils, an experience that exists and operates independently of attempts to master the subject matter. The etymology of the word "interest," namely, *inter* and *esse*, to be between, suggests, if it does not adequately convey, the idea. Interest indicates that no

## INTEREST

gulf exists between material to be learned, lesson material, and the concrete mind of the pupil — that the mental powers and tendencies find themselves at home in the material of study, that the material awakens congenial responses in the self. So regarded, an interest in a problem, a topic, a subject, is evidence that there is a vital union between the student and his study. Its opposite is the feeling of alienation and repulsion that accompanies the presentation of matter that is foreign to the experience of the student.

Psychologically, interest and attention are closely allied events. They are frequently regarded as the subjective and objective aspects of the same activity. That is to say, the effective assimilation of new material into the course of experience is interest when viewed from the standpoint of the mental affection, the emotion and personal attitude, that accompany it. It is attention when viewed as the active outgoing of mental habits in grasping and mastering the subject matter. Other views regard interest as prior and as the source of attention; or, *vice versa*, conceive interest as the emotional result of a prior act of attention. All views, however, acknowledge the intimate connection of the two, and it is this close connection which is the significant matter for education. Like attention (*qv*), interest as a state of mind depends upon the proper balance of the old and the new in experience. Where the material is almost wholly new, there is excess of stimulation; the responsive powers of mind are overwhelmed and confused. Discouragement and aversion result. As the term "aversion" implies, there is a strong tendency for the mind to turn away and devote itself to some more congenial and rewarding topic. Even if this tendency is partly overcome, it means divided, and consequently wasted, energy as compared with the unified, whole-hearted activity where interest is naturally and directly sustained. On the other hand, the thoroughly familiar denotes the mastered, the habitual. It sets off tendencies that work automatically and mechanically. If there is also a new factor about which habits may play, these habitual tendencies will furnish the background for intense and concentrated interest. But if there is no stimulation beyond that evoking the established habits, the result will be ennui, monotony, routine. The effect is that of walking in a treadmill where nothing new is achieved. Put in other words, a certain degree of difficulty, a certain amount of obstacle to be overcome, enough to set the problem of a readjustment of habit, is necessary for sustained interest. If the self is to put itself wholeheartedly into what it is doing, its powers must be thoroughly awakened, and this is impossible without a challenging difficulty.

The fact just stated throws light upon the relation between desire (as standing for in-

terest) and effort, and helps place the relation of the doctrine of interest to that of discipline. As long as children "live in the present," they are absorbed in their immediate concerns. All their powers are directed at and, so to speak, discharged upon, the immediately present stimulus. There are no *ends*, that is to say, no conceived results to be reached, after an intervening time, through the controlled adaptation of conditions as means — or the end lies in such a near future that but little thought has to be given to the management of intermediate conditions.

This state of *immediate* interest characterizes the "play activities." When more remote ends are entertained as objects to be reached by the consistent and sustained maintenance of a series of acts that, of themselves, lack immediate interest, (but that are of interest because of their importance for the remoter end in view), we have *mediate* interest. Being dependent on an idea, mediate interest involves an intellectual interest in a way, in which the emotional heightening accompanying direct absorption does not. The interest in a more or less prolonged series of acts is dependent upon the persistence of an *idea* — the thought of an end and the thought of the bearing of the immediately present upon the attainment of this end. The control of the activity, and the source of interest, reside in what is *conceived*, what is physically absent, not in perception or what is physically present.

The remoteness of the end in time means of course increase in the number of difficulties to be dealt with, there is a series of difficulties to be dealt with one after another. Consequently the seriousness, the depth of the interest of the self in its objective — its aim — is continually being tested and retested. If the interest is slight and passing, the emergence of a difficulty in an unexpected form or in an unusually strenuous way will distract the mind from its pursuit, and lead to taking up something which has an immediate, non-intellectual value. On the other hand, if the self is deeply concerned with, thoroughly committed to, its object, each successive obstacle will deepen the sense of the importance of the object and increase the *effort* expended in behalf of its realization. In many cases, perhaps the majority of cases, there will be an oscillation — a tendency to surrender the end in behalf of some more immediately interesting object, and a tendency to cling to the end, to emphasize its importance, in order to enlist further effort in its behalf. Under these conditions, while physical effort will go to the means for reaching the end, moral and intellectual effort will be directed to sustaining the idea of the end in such force as to give it motive power.

We have here all the elements of a seeming conflict of interest and effort, with immediate attractiveness, immediate agreeableness on the side of interest, while serious and important

values are all on the side of effort. Hence the situation has been frequently completely misinterpreted in theories of education, with respect to both its intellectual and its moral implications. That is, interest has been regarded as an inherently unworthy and objectionable factor, operating only as a temptation away from the objectively important; it has been identified with the attractive and swerving power of the immediately pleasurable over against what thought — or reason — shows to be *really* worth while. This implies that the objectively valuable end is totally lacking in inherent interest, so that sheer effort of the will has to be relied upon as the sole motive for keeping the self in its right course — for keeping it struggling against the seductions of "interest."

The previous analysis should reveal what is at fault in this interpretation. What sustains effort is not sheer appeal to will power, but interest in the end — the interest that is indirect and intelligent, as distinguished from that which is immediate, purely personal, emotional, and sensuous. The genuine educational need is, therefore, not to eliminate interest, but to foster the *indirect* interest, the interest attaching to the end in view, to make it more powerful than the immediate interests which would, if they became motive forces, take the self away from its end, and reduce action from the plane of thought to that of sense. The import of immediate interest is quite different before and after reflection and the conceiving of remote ends have entered in. When thought is not playing an important part, or when the situation is such that there is no need that it should play a considerable rôle, immediate interest is simply an indication of hearty, wholesome outgoing activity of the self, a sign of its ability to identify itself with its surroundings, to express itself therein and to find itself reflected by the environment. It remains a fundamental trait of all æsthetic and artistic manifestations. Moreover, in the degree in which the interest in the end is seriously sustained and worked out, it tends to transfer itself to interest in the means of reaching the end. A new type of immediate interest is thus developed, one which is as direct, as hearty and spontaneous, as the earlier personal and sensuous interest, but one which depends upon the intervention of thought. When an individual becomes intensely and sincerely interested in an end which reflection holds up, the sense of separation between means and end tends to disappear. The means become saturated with a sense of the value of the end; and the end is so identified with the means of achieving it that it ceases to seem remote and far away, every one of the present means represents, embodies it. This mutual interpenetration of means and end is constantly exhibited in scientific pursuits as well as in endeavors to achieve wealth and political distinction. But there is

often a period between the original absence of the end dependent upon reason and the final unification of interest in intellectual end and existent means, when the thought of an end pulls one way while the immediately present conditions pull in another. In this intervening state, there is temporarily a real conflict between thought, standing for continuity of purpose, and reason, immediate interest, standing for the agreeable, the pleasurable, the direct urgency of desire. But, as already indicated, the effective way of dealing with this critical juncture is not to attempt the hopeless task of crushing out all interest by sheer effort in behalf of something totally lacking in interest; it is to reinforce by all possible means the interest in the end, so that its interest may fuse with that of means for its attainment.

We are now in a position to perceive the true and false signification of discipline in connection with interest. A disciplined mind is one that can hold to a train of thought in spite of the attractions and distractions of irrelevant considerations, it means power to attend to the conceived, and to relate the perceived (and what the imagination incidentally presents) to the conceived. A disciplinary process in education is one which tends to bring about the state of mental control. True discipline, in short, is distinctly a matter of intellectual attitude and method—the power to keep thinking in dominant control of the situation when the situation needs reflective survey and estimation. Since this clearly involves the overcoming of obstacles and the holding of mind to what is directly more or less disagreeable, the false notion of discipline arises by ignoring the function of intelligence as the source of concentration, order, and regular sequence, thereby identifying discipline with sheer effort directed to the disagreeable. Hence disciplining methods are supposed to be effective whenever a person is forced to occupy himself with whatever is uninteresting and naturally repellent. Difficulties are multiplied for the mere sake of having difficulties, tasks are assigned as tasks to discipline *will*, the power of attention to the repellent. The error is in isolating will or the power of attentive application from thought as the function of sustaining remote ends and of bringing them into close connection with means, or existent conditions.

This fallacious conception of discipline which relates it to effort to the exclusion of habits of thought is strengthened by an opposite error. One school of educators, noting the waste that comes from trying to work against interest, substitutes appeal to momentary emotional agreeableness, for both appeal to will and to the interest of the remoter end. Like the so-called disciplinary school, it fails to denote that thought, that ideas of ends or purposes, holds the key to the situation. By interest it means various devices that tend to

conceal the real end from view, that lessen the need of serious thinking, and that place the control of action in the direct stimulation of present conditions. Interest thus comes to mean a sort of sugar-coating over of difficulties. Since this method inevitably relaxes discipline in its proper sense—that is, the power to utilize thinking as an effective method of guidance of action—its failure to develop continuity of application and serious industry evokes a reactionary appeal to the method of securing “discipline” by the assignment of obnoxious tasks. Then as this method fails to secure motivation and genuine regard for the materials of instruction, it in turn calls out recourse to the method of emotional stimulation. The only way out of this vicious circle is the recognition of the importance of the intellectual factor, the idea of a more or less distant end, and the necessity of reinforcing interest in it as the controlling factor.

We have noticed above that indirect interest involves an intellectual interest. At the outset, this intellectual interest, while genuine and indispensable, is secondary to the interest in achieving an end or purpose—to a practical interest in the broad sense of “practical.” The transfer of interest from ends to means is, however, one of the commonest phenomena of experience, having its traditional illustration, on its undesirable side, in the miser’s transfer of interest in what money will do to the money itself. But the principle has also its positively valuable side. It shows itself whenever there is developed an interest in thinking for its own sake, an interest in conducting reflection, pursuing inquiries, with no ulterior aim. Different minds differ immensely in their susceptibility to this transferability, but whenever it occurs we have strictly intellectual interests. A certain amount of intellectual interest for its own sake is necessary to a proper degree of detachment, of generosity and impartiality, of comprehensive survey of the field, even in practical matters. Hence it is an end to be cultivated in educational procedure. Some minds are as likely to fall into excess upon this side, however, as others are in the narrowly practical, unintellectual direction. Such minds become academic and scholastic, “abstract” in the bad sense of that term; their knowledge is divorced from influence upon action, theory is separated from practice. Hence ideas remain untested and unfertilized by application, while practice remains hard and narrow because not enlightened and inspired by breadth of intelligence. Owing to various historic circumstances, most schooling has come to favor unduly the fostering of the pale academic type, at the expense of those individuals whose natural and persistent interests are more active and objectively constructive. (See *ACTIVITY and CULTURE*.)

We have approached the subject of interest from the psychological side. This implies, how-

ever, its objective side. The term "interest," or an interest, is constantly used to denote that in which interest is taken. It is used as synonymous with a concern, a value, a dominant direction of thought and action, an occupation that is persistently important. Thus we speak of business, of science, of art, of religion, of politics as interests. This objective use of the term "interest" bears out what was originally said of interest as the point of identification of mind with its object, or subject matter. This identity may be approached and discussed — as above — from the side of the mind, but it may be equally well approached from the side of the subject matter in which the self finds its powers sustained and fulfilled. The fundamental thing, educationally, is that interest has both of these aspects. As a guiding principle or norm in education its influence should be to protect educators from two harmful abstractions. On the one hand, from viewing mind as something which can operate and manifest its nature all by itself in a mental, subjective region. As against this notion (and the many educational practices connected with it) the doctrine of interest holds up to view the need of subject matter of content in art, in science, in literature and history, in technical constructive activities, etc., in order that mind may be active and be fulfilled. On the other hand, there is the fallacy which makes the mind equally indifferent to subject matter, which supposes that if it only *will* (if it but will choose to do so), it may apply itself to any subject matter, and that any regard for the inherent choice and spontaneous direction of mind is a concession to a weak and enervating principle. As against this notion, the doctrine of interest is important in maintaining the fact that subject matter is assimilable and capable of having educative influence only so far as it is caught up into and held by certain inherent active tendencies of the self, thereby becoming an interest, a vital concern, a significant occupation of the self.

**INTEREST** — In medieval Europe the objection to paying for the use of money was so

great that the borrower was supposed to return only the amount of his debt. If, however, he delayed, he was held to pay as compensation a sum representing that which was between ("id quod interest") the creditor's position because of the delay and that which he would have occupied if the debt had been promptly paid. Hence our word "interest."

The taking of interest is very ancient. From the old records on the clay cylinders, it appears that the usual rate in Babylon was a shekel on a maneh, or about 16 per cent, although it ran even higher than this. Tablets as early as the seventh century B.C. relate that interest was computed either by the month or by the year. In ancient India it appears that 15 per cent a year was not uncommon, and six different forms of interest appear, including compound interest. In the writings of Bhaskara (*q v*) problems appear like the following: "If the interest of a hundred for a month and one third be five and one fifth, say what is the interest of sixty-two and a half for three months and one fifth?" In Greece the interest (*τόκος*) was apparently not restricted by laws but the rate varied from 12 per cent to 18 per cent. In Rome, interest was called *fenus*, or, later, *usura* (generally in the plural, *usurae*). The rate was at first unrestricted, but the *Duodecim Tabulae* (450 B.C.) limited it as between Romans to 8½ per cent. The *Lex Genucia* (342 B.C.) prohibited the taking of interest, but, like the medieval law, it was probably laxly enforced. In later Roman times the Eastern custom of monthly interest came into use, the ordinary rate being 1 per cent, or 12 per cent per annum. In Cicero's time 48 per cent was allowed, but by the time of Justinian this had been reduced to 6 per cent. Some idea of percentage appears in the *usura centesima*, or 1 per cent per month. The "id quod interest" of the Middle Ages came in the thirteenth century to be agreed to in advance, and Leonardo of Pisa (see FIBONACCI) gives problems involving 20 per cent. Matthew Paris says that in his time 10 per cent was exacted every two months, and that thus the unscrupulous "circumvented the needy in their necessities, cloaking their usury under the show of trade." The supposed antagonism of the canon law to all forms of interest was seriously questioned in the fifteenth and sixteenth centuries (as by Franciscus de Platea, *Opus de restitutionibus usurarum et excommunicationibus*; Johannes Nieder, *Tractatus de contractibus mercatorum*, and others), and as a result the subject appears in many of the early printed arithmetics. For example, Calandri (1491) speaks of lending money "per 3 anni a 10 per cento lanno." Some of these writers introduce the subject under protest, as a "diabolical" one, as in the case of Cataneo (1546), Gemma Frisius (1540), and Pagani (1591). From that time to the present, the topic has appeared in practically all arithmetics.

Compound interest was known to the Romans, and was not forbidden by the earlier laws. It appeared in printed arithmetics in the sixteenth century as interest "*à capo d'anno*" (compounded from the first of each year), and "*à capo d'alcun tempo*" (compounded from the beginning of some other fixed period). From the Italians the latter passed over to the French as "*merite à chef de terme*" (Trenchant, 1566), and to the Dutch as "*interest op interest*". It was unjustly charged that compound interest was chiefly used by the Hebrews ("*vsitato da gl'hebrei ne suoi Banchi*," as Pagan writes in 1591), and it was occasionally called by their name ("*che chiamano Giudaica*," as the Italian edition of Gemma Frisius misspelled it in 1567, "*Een loodtsch profijt*," as Vander Schuere gave it in 1600).

The method of reckoning simple interest has never been settled. The year is about 365½ days long, and hence there is practically no such thing as exact interest. For convenience 360 days are taken for the year in ordinary computations, and 365 days for more accurate work. Tables were early constructed to facilitate computation, and they appear in many of the first printed arithmetics.

As an educational topic, interest usually appears among the early applications of percentage. The subject has become unduly complicated in the schools through the elaboration of problems requiring the finding of the time, rate, or principal. The chief emphasis should always be laid upon the finding of the interest, the other cases demanding relatively little attention.

The growth of banking facilities has developed short-term notes to such an extent that the subject as formerly taught is losing much of its practical value. Interest is now commonly paid every thirty, sixty, or ninety days, or else every year, and we may reasonably expect a gradual simplification of the subject as taught in the schools. D. E. S.

**INTERFERENCE OF HABITS.** — Mental processes of all types are so interrelated that no single phase of mental life can develop without influencing all of the other types of activity. The same is true in general of the physiological processes of body activity. Thus, if one moves a certain portion of the body, the circulatory system responds by abstracting blood from other parts of the body and sending it to the exercised region. If now the individual trains himself so that a certain portion of his body, or a certain type of thought, is highly cultivated, he may thereby interfere with an equally high development of other phases of his nature. Examples of interference of mental habits can readily be drawn from ordinary experience. The individual who is very much interested in natural objects is not likely to develop an equal degree of interest in literary

forms. The individual who has learned one form of handwriting cannot so readily take on another type. In short, the negative side of habit cultivation is one which deserves very full recognition in educational discussions. Whenever a habit has been perfected, the possibilities of developing other habits are correspondingly curtailed. When two habits must be cultivated side by side and mutually interfere with each other, they require more exercise for their perfection than would be required for a single habit unaccompanied by the interfering type of activity. The whole matter here under discussion relates itself to the problem of formal discipline (*q.v.*). C. H. J.

**INTERMEDIATE HIGH SCHOOL** — A term applied, in a few cities, to a school intermediate between the elementary school system and the high school proper, and including parts of each. The city of Berkeley, Cal., offers a good illustration of the use of the term. Here the first six years of the elementary school system are taught by grade teachers, and along grade lines. The seventh, eighth, and ninth years are grouped together, in separate buildings, termed Intermediate High Schools, and are taught by teachers who have had college training, and on the departmental system. (See DEPARTMENTAL SYSTEM.) The course of instruction during these years is materially enriched, and certain options are offered. These schools also serve to make the transition to the high school easier. The tenth, eleventh, and twelfth years then constitute the regular high school. The plan serves also to relieve the pressure for seating space in both the elementary schools and the high schools, as two or more intermediate high schools may be provided for in different parts of the city, and these serve to take two grades out of each elementary school and one out of the high school. While not saving anything in classrooms, it provides better for the educational needs of the city. The main argument for the plan, however, lies on the educational side. E. P. C.

**INTERNAL SPEECH, INNER SPEECH.**— The efforts to carry on ideational processes are accompanied by certain incipient contractions of the vocal organs. These incipient contractions of the vocal organs can be shown to be of the highest importance in the formation of ideas. Whenever they are interrupted, the individual is handicapped in memory and in clearness of recognition. The distinction between internal speech and ordinary speech is not great in a child. Here the tendencies are always strong toward external, complete expression, but as development goes forward the individual suppresses more and more the grosser forms of activity, and carries on his mental processes with the aid of internal speech alone. C. H. J.

**INTERNATIONAL CONGRESS OF HOME EDUCATION.** — See PARENTHOOD, EDUCATION FOR.

**INTERNATIONAL CONGRESSES OF EDUCATION** — Educational congresses have been held in connection with practically all the international expositions (*qv*) of the last half century. There was an educational conference in connection with the international exposition held at London in 1851, at which representatives from Germany, France, and the United States joined English educators in the discussion of the educational aspects of the exhibits and other topics of international interest. The recently organized kindergarten (*qv*) in Germany was one of the subjects discussed at the London conference. Americans who participated in this conference were Henry Barnard, Walter R. Johnson, and Mrs. Emma Willard (*qv*). There were also conferences on elementary, secondary, and higher education at the Paris expositions of 1855 and 1867. President F. A. P. Barnard (*qv*) was the official representative of the United States at both congresses. Somewhat broader in scope and more international in character was the conference held at the Vienna exposition of 1873. The various phases of infant education and child welfare — the crèche, the *salle*

*d'asile*, the kindergarten, the care and training of defective children — the blind, the deaf, and the feeble-minded; elementary education, school gardens, and sex in education were among the subjects presented. The United States was represented by John Eaton, John D. Philbrick, and Edward Seguin (*qv*).

Four international congresses of education have been held in the United States, — Philadelphia, 1876, New Orleans, 1885, Chicago, 1893, and St. Louis, 1904. At the international conference on education held in connection with the exposition which celebrated the first anniversary of American Independence, thirteen foreign countries and most of the states of the American Union were represented. Sir Richard Barry of Australia presided, and Commissioner of Education John Eaton organized the program, which included ten topics for discussion, — courses of study, methods of instruction, supervision of schools, pedagogical museums and exhibits, technical education, training of teachers, the kindergarten and elementary schools, university and professional education, and the education of women.

The third Paris conference was held in connection with the international exposition of 1878. Besides the general congresses there were numerous special conferences on the education of the blind and deaf, technical and industrial education, etc. The United States was represented by John D. Philbrick, James P. Wickersham, and F. A. P. Barnard (*qv*).

There was also a general conference on education at the Brussels exposition of 1880, at which William T. Harris represented the United States.

The second American congress was held in connection with the international cotton exposition at New Orleans, February, 1885. John Eaton, Commissioner of Education, presided. Besides the general meetings, there were departmental meetings devoted to elementary, secondary, and superior instruction, school architecture and hygiene, care and training of defective, dependent, and delinquent children, national aid to education, care of the Indians, and educational journalism. The fourth Paris congress was held in 1889, at which M. Gréard (*qv*) presided. There were three general congresses of education — primary, secondary, and superior instruction — and six special congresses — physical education, commercial and industrial education, psychology, mathematics, and chemistry.

The third American congress was held at Chicago in 1893 in connection with the Columbian exposition and under the auspices of the National Education Association (*qr*). William T. Harris presided. Besides the general sessions there were fifteen departmental congresses, including higher, secondary, and elementary education, experimental (genetic) and rational psychology, school supervision, manual training; the kindergarten, training

## INTERNATIONAL CONGRESSES

of teachers, and educational journalism. Most of the countries of the world were represented. The fifth and last Paris congress was held in 1900. It included practically every phase of educational activity, and conferences (more than twenty) were in session for two months.

The fourth American congress was held at St. Louis, September, 1904. Its purpose was to "bring to the consciousness of the world the too much neglected idea of the unity of truth." In consequence the congress was organized into seven general divisions — normative science, historical science, physical science, utilitarian science, mental science, social regulation, and social culture. These divisions were again subdivided into a great number of departmental conferences (128 in all), in each of which the fundamental methods and the progress of the century formed the basis of the addresses. A second international congress of education was held at Brussels in 1910. Besides the general congress on popular education there were numerous departmental congresses.

In addition to these general congresses of education, there have been a number of special congresses, such as the International Congress of Home Education, with meetings at Liège in 1905, Milan in 1906, and Brussels in 1910; the International Congress of School Hygiene at Nuremberg in 1904, London, 1907, and Paris, 1910; the International Congress of Psychology at Paris, 1889, London, 1892, Munich, 1896, Paris, 1900, Rome, 1905, and Geneva, 1909; the International Congress of Technical Education at Bordeaux, 1886, Paris, 1889 and 1900, London, 1897, and Brussels, 1910; International Congress of Educators of the Deaf at Paris, 1878 and 1900, Milan, 1880, Brussels, 1883, Chicago, 1893, and Edinburgh, 1907; and International Congress for the Education of the Blind at Paris, 1900, Brussels, 1902, Naples, 1909, and Cairo, 1911.

**INTERNATIONALISM, FOUNDATION FOR THE PROMOTION OF, THE HAGUE, HOLLAND** — The main purpose of this Foundation, organized in 1910, is to promote internationalism in movements for intellectual and social progress, and is part of the broader movement for world's peace. It aims to establish permanent international organizations dealing with related problems and grouped according to related interests. Three such bureaus already exist: Bureau de la Commission permanente des Congrès internationaux de Médecine (1909), Bureau permanent de la Fédération internationale de Pharmacie (1910), and the Bureau permanent de l'Institut international de Statistique (1912). Other bureaus are contemplated for pure science and letters, hygiene, and technology. The leading spirit in the movement is Dr P H Eijkman, director of the Preliminary Office of the Foundation and author of *L'Internationalisme médical* and *L'Internationalisme scientifique*.

**INTERPRETATION** — Every impression has added to it in individual experience certain meanings, which are derived through comparison and memory. These added phases of experience which enlarge the significance of a given impression are called interpretations. Whenever, therefore, an impression is enlarged upon through mental activity we have an example of interpretation. In common usage,

## INTERVAL

this term is employed to cover such cases as translation of a passage from a foreign language where the additional factors are the elements of the vernacular which are used to explain the foreign terms. An example of psychological meaning is that of a sound which in addition to being heard is amplified by association and understood as a word. C H J

**INTERVAL.** — The lapse of time between one event and another is known as a temporal interval, the qualitative difference between one tone and another is known as a tonal interval, distance in space is designated a spatial interval. In general, any transition from one point to another involves the traversing of an interval. C H J

**INTERVAL.** — See MUSICAL TERMS

**INTOXICATION** — In the broadest sense any kind of poisoning, usually restricted to the mental and physical effects following an overpowering dose of poison, and popularly used to designate the mental condition following the continued or excessive use of alcoholic liquors.

Two kinds of intoxication are recognized, that of endogenous and that of exogenous origin. Endogenous intoxication is due to the poisons (toxins) manufactured within the body by its different organs, such as those of faulty metabolism from disease of the liver or of the gastro-intestinal tract, and the condition is then known as or called autotoxic. The exogenous intoxications are due to the introduction into the body of substances that act deleteriously upon the organs, and especially upon the nervous system. Intermediate between these two kinds of intoxication are the intoxications due to toxins produced by micro-organisms. In this form of intoxication the micro-organisms are introduced from without, but the formation of the toxins takes place within the body. Because of the latter fact these intoxications are usually classed with the endogenous.

**Endogenous Intoxication.**—Normally, digestion is the chemical breaking up of the food into simpler compounds that may be absorbed and utilized for the upbuilding and the repairing of the body. Abnormal conditions occur, however, in which the chemical division of the food does not stop when the food is fit for bodily consumption, but continues to the elaboration of some products that are deleterious to the organs. With the normal working of the kidneys and the liver most of these products are taken care of, are rapidly changed into innocuous compounds and excreted. In the normal working of the body tissues are broken down and the metabolic products are eliminated

## INTOXICATION

through the joint action of the kidneys and the liver. It requires the normal activity of both of these organs, and of many others, to keep the body in a normal chemical condition, and if these organs be diseased, there may be too great a formation or a lack of elimination of the waste products, with the result of poisoning all the tissues. This is in an autotoxic condition.

The auto-intoxication effects from diseases of the thyroid glands are well recognized. The congenital absence of the gland is productive of imbecility (*qv*) of the form known as cretinism (*qv*). In exophthalmic goiter hallucinations and states of anxiety and of agitation are found. In myxædema, the mental symptoms are stupidity, apathy even to the degree of complete dementia, attention, apprehension, association, and memory defects. In this connection it is worthy of note that Kraepelin at first grouped dementia precox with thyrogenous insanity, and there have been repeated attempts to explain all the symptoms in dementia precox from an autotoxic standpoint.

**Exogenous Intoxication** — Most drugs, when taken in sufficient quantities, produce mental and physical symptoms that may be called intoxications. Certain drugs have this property more than others and are called intoxicants, hypnotics, narcotics, and anæsthetics (See ANÆSTHESIA). Among these we find ether, chloroform, chloral and its derivatives, sulphonal, trional, paraldehyde, urethane, veronal, hedonal, ethyl and methyl alcohols, and nitrous oxide. Opium and its derivatives (*eg* morphine), cocaine, atropine, hyosine, salicylates, mercury, lead and many other substances give similar symptoms of intoxication. Some of these produce intoxication effects only after long-continued use, and the effects are somewhat similar to those of chronic poisoning. Lead poisoning may result in a condition similar to that of alcohol. Hallucinations, agitation, anxiety, incoherence, disorientation, and intellectual defects may be present. Morphine brings about hyperæsthesias, hallucinations, slow and slightly incoherent mental state, but usually memory is not impaired. For the effect of alcohol see ALCOHOL, USE AND PSYCHOLOGICAL EFFECT OF.

Although most of the intoxications of exogenous origin are found in adults, it should be remembered that children may be similarly affected. The use of soothing syrups, of certain patent medicines, and even of physicians' prescriptions containing any of the drugs mentioned above may produce intoxication. It is well known that soothing syrups contain morphine in some form, and once the habit is formed in a child we have a condition similar to that of the adult morphine fiend. Many patent medicines contain alcohol, and from their use (or abuse) there may result an alcohol intoxication, usually of a chronic nature.

Whenever a child exhibits any degree of stupidity, of incoherence, or of agitation, and always when hallucinations are present, a careful examination regarding the food and drink should be made. Special attention should be paid to the quantity of candy and its nature, for it is known that alcohol may be formed in the intestine from ingested sugar, and it may be introduced in the form of "brandy drops," which are not uncommonly sold to children. Lead in toys and in drinking water is another common intoxicant, but the symptoms are usually chronic. S. I. F.

**INTROSPECTION.**—This is the method of psychology whereby the individual observes his own internal mental processes. For example, one has a feeling of pleasure, and when he notes this fact and observes its character he is introspecting his own mind. Attention has always been called to the difficulties of such introspective observation. The will to turn one's attention upon one's self interferes with the normal flow of normal processes. Most introspection is therefore retrospection. Formerly it was said that introspection was the only method of psychological investigation. With the development of experimentation in psychology it has become obvious that one can study the mental activity of another individual without coming into direct contact with the inner mental processes involved. C. H. J.

**INTUITION.**—A name given to direct, as distinct from mediate or logical knowledge. In the history of thought two types of intuition have been discriminated: sense perception and rational perception. With respect to the former, the chief problem has been whether it is in and of itself a mode of knowledge, or whether it is a mode of judgment, that is, of inferential interpretation. If the former, there is such a thing as knowledge without thinking; in the latter case, the instantaneous character of a perceptual intuition expresses the fact that recurring previous inferences have finally formed an automatically operative habit. The perception is then, in its strict sense, a *re-cognition*, a knowing in terms of prior knowings that involved judging. In this controversy, the party that held that perception was acquired rather than primitive

intuitive knowledge is admitted to have been successful. However, as far as the philosophical point at issue was concerned, this conclusion was offset by recourse to sensation as a substitute form of immediate knowledge. The doctrine of rational intuition was first systematically developed by Plato. He felt the need of some way of knowing which should combine the rationality of discursive, or demonstrative, knowledge with the directness and vitality of pure immediacy. So he introduced the conception of a face-to-face perception by pure reason of ultimate absolute essences (see **IDEA**). This intuition involved a mutual interpenetration of knower and known and an assimilation of the former to the latter. This motif was developed by the Neo-Platonists in their conception of an ecstatic vision transcending all logical categories, and by the mystic school of Christian theologians in the idea of the beatific vision of God.

In the Platonic tradition rational intuition was an envisagement of absolute reality, and implied a quasi-mystic factor. After the collapse of the doctrine of innate ideas (*q. v.*) the rationalistic anti-mystic school introduced the idea of rational intuition of abstract truths, like those of morals and mathematics. This doctrine of an immediate certitude of first and necessary truths became the bulwark of the Scotch school in opposition to the skeptical turn given empiricism by Hume. Kant employed the notion of an intuitive understanding as an ideal of knowledge, unattainable but useful in providing a limiting notion by which both sense perception and reflective judgment could be criticised and their pretensions to yield more than relative knowledge exposed. In contemporary thought Bergson has introduced an interesting variation of the idea of rational intuition. According to him, logical or discursive intelligence has been evolved in the interests of action, and is accordingly quite unadapted to the speculative task of grasping Reality in itself. Intelligence and instinct represent, however, diverging lines of evolution out of a common reality; while a sort of vague penumbra of instinct still surrounds the clear-cut outlines of intellectual knowledge. By retracing that phase of the evolution of reality which has taken the road of instinct, human beings may by an extreme effort of will bring about a fusion of intellectual results with the residual penumbra of instinct they still directly possess, and thereby secure at least a fleeting glimpse of the inner creative impetus of reality itself. J. D.

See **EMPIRICISM**; **IDEA**; **INNATE IDEA**; **MYSTICISM**; **NEO-PLATONISM**; etc.

**INVENTION.**—A general term referring to that type of mental activity whereby one departs from experience which he has had and works out a novel combination (See **IMAGINATION**, **IDEAS**) In its usual form invention

realizes itself in the construction after the pattern of the mental recombination of some external mechanism. Thus, the inventor of a machine, after working out the relations between the parts of the machine in his mind, realizes his ideas in some actual construction.

Royce has shown that the range of individual possibility of invention seems to be limited by certain habits of the individual's life. One cannot deliberately invent a new form without exhibiting his natural tendency to operate within a fairly limited range of possible forms. That individual who is capable of the largest number of unique combinations is said to be most inventive. His mental activities are closely related in type to biological variations (q v.).

**INVENTIONAL GEOMETRY.** — A term rather loosely used in the United States to designate an introduction to elementary geometry, the pupil being led to discover for himself the theorems he is to prove, and to invent the proofs. It is substantially the same as the heuristic teaching of the beginnings of geometry in the German schools. The Germans have an expression, *Vorschule der Geometrie*, that happily represents this initial stage. In this are developed the fundamental concepts of plane and solid geometry, and the mensuration of the simplest forms. This is followed by easy propositions relating to angles and triangles, with simple constructions by the aid of the ruler and compasses. This is taken up in the spirit suggested by the name Inventional Geometry. The latter term is not a fortunate one, since it gives the impression that it refers to a kind of geometry different from that of the secondary school, as is the case with the projective and descriptive geometries, when it really refers only to a method of teaching a part of that geometry to young pupils. For this reason it is not liable to be used extensively. The spirit suggested by the term is, however, worthy of serious attention. Up to the present time the work in geometry in the elementary grades has been little besides mensuration, and under the present school conditions there is not likely to be any change in this limitation. With departmental teaching in grades seven and eight it would be quite possible to introduce the German plan.

Inductive geometry is, as the term indicates, substantially synonymous with inventional geometry as it is usually considered. The first steps in any science may properly be inductive, leading to the discovery of probable truths. This should be followed by the deductive stage in which the probable becomes the veritable

D. E. S.

**INVOLUNTARY ACTION.** — That form of behavior in which no conscious choice or deliberation is present.

See WILL.

**INVOLUTION.** — The operation of raising a number to a power. The word comes from the idea of rolling or involving a number into itself by means of multiplication, and was not common until rather recently. The earlier arithmetics proceed at once to Evolution (the extraction of roots) without any preliminary work on Involution. Thus in *De Arte Supputandi* of Tostall (1522), division (*De partitione*) is followed by roots (*De quadrati et cubi lateribus investigandis*). The reason for the presence of a chapter on Involution in arithmetic is to be sought in the reflex influence of algebra on the subject. There is no need for the word in elementary arithmetic, nor for any more than a passing reference to the subject, together with the expansion of  $(a + b)^2$ , if square root is to be studied, and of  $(a + b)^3$ , if cube root is included. It may confidently be expected that the topic will cease to have any separate treatment in elementary arithmetic.

D. E. S.

**IOWA, STATE OF** — Originally a part of the Louisiana purchase, and organized as a part of the Territory of Missouri in 1812, Michigan in 1834, Wisconsin in 1836, and as the separate Territory of Iowa in 1838. It was admitted to the Union in 1846 as the twenty-ninth state. It is located in the western portion of the North Central Division, and has a land area of 55,475 square miles. In size it is one fourth larger than Pennsylvania, and nearly as large as the six New England states. In 1910 Iowa had a population of 2,224,771 and a density of population of 40.01 persons to the square mile.

**Educational History.** — The first school in Iowa was taught in 1830, near the present site of Keokuk. By the time of the organization of the territory in 1838 some forty schools were in existence in different places. All of these were private or subscription schools. The first school building, a combined church and schoolhouse, was erected near Dubuque in 1833. By the time of the admission of Iowa in 1846, there were one hundred log schoolhouses in the state. In January, 1838, five seminaries were chartered for Iowa by the Wisconsin Territorial Legislature, but no means of maintaining these schools was provided. Two colleges were also chartered at the same time. The first legislature under the territory of Iowa enacted the first school law in 1838. This provided for the formation of districts, the establishing of schools, and authorized the voters of each district to levy taxes for schools up to a total of five mills and \$10 per person. The second legislature in 1840 enacted a law which made provision for

free public schools, but the law was in advance of public sentiment, and practically remained a dead letter. The census of 1840 reported but one academy and sixty-three common schools in the territory. In 1841 the office of Territorial Superintendent of Public Instruction was created, but the superintendent made but a single report, and the office was abolished the next year. Though the territorial governors urged important action, little was accomplished during the territorial period.

The state constitution of 1846 made careful provision for the establishment of a system of state schools. A Superintendent of Public Instruction was provided for, to be elected for three-year periods by the people, the General Assembly was instructed to provide for a system of common schools by which a school should be kept up and supported for three months in each school district each year; and the school and university funds were enumerated and declared perpetual funds, the income only to be used. At the time of admission to the Union there were 416 school districts in the state. The law of 1847 made partial provision for carrying out the instructions of the constitution. The election of a Superintendent of Public Instruction was provided for, who was to look after the school fund and report to the legislature, means of organizing school districts, electing directors, raising funds for schoolhouses, the inspection of schools, and the examination of teachers by the inspectors were also provided for. School fund commissioners were to be appointed in each county to manage the county's share of the school fund and to report to the State Superintendent. In 1848 the legislature authorized a district tax both for schoolhouses and support, and in 1857 towns and cities were authorized to provide a graded school system, including schools in which languages other than English might be taught, and to levy a tax up to five mills therefor. Notwithstanding these efforts, the schools continued to be supported in large part by the rate bill until 1858, when they were made free, while inspection and examination of teachers existed little more than in name. In 1857 there were 3265 school districts in the state.

In 1857 a new constitution was adopted which made detailed and very advanced provision for a strong state school system. The constitutional provisions relating to education were divided into two parts. The first made detailed provision for a State Board of Education, to be elected by the people, and constituted it a legislative body with power to make laws and rules and regulations for the schools, levy taxes, make appropriations, and to appoint a Secretary, who was to supersede the Superintendent of Public Instruction and act as the executive officer of the board. This board was charged with the duty of providing for a system of common schools whereby a common school should be kept up in each school district

at least three months each year. A final clause gave the legislature power at any time after the year 1863 to reorganize the board and abolish its legislative functions, and this was done in 1864. The second part of the article on education made detailed provision for the care of the school lands and school funds, provided for its increase, and for the distribution of its income. In the preceding year the Governor of the state had been authorized to appoint a commission to revise the school laws of the state and to provide an efficient school system for Iowa. Horace Mann and the Chancellor of the State University, Amos Dean, were the two commissioners who framed the report. The commission submitted their recommendations in the form of a bill, December, 1856, but it was not until early in 1858 that any action was taken. The recommendations were then enacted into law by both the legislature and the new Board of Education. The "rate" was abolished, and the schools were made free to all the children in the state, the office of county superintendent was established for the examination of teachers and the visitation of schools, county institutes were to be established and to receive aid, county high schools were authorized, and the township was made the unit of organization, and the school districts were reduced to subdistricts. Later, in 1858, cities and towns were allowed to organize into independent districts, and since then this objectionable permission has been extended and extended, until now any village of 100 residents may segregate itself and form an independent district, and thus escape the burden of general taxation. From 334 independent districts and 1176 school townships in 1870, the number has increased to 3766 independent districts and 1182 school townships in 1905. The new law of 1858, providing for taxation for free schools, was enacted at a time of great financial stringency, when the people found it difficult to accept any new financial burdens, and the new legislative State Board of Education did a valuable service, during the few years of its existence, in steadying affairs and in upholding the new law until the people could get used to it and accept it. In 1864 the board was abolished and the office of State Superintendent of Public Instruction was revived. This law marks the establishment of the present school system, the changes since then having been nearly all in the nature of the expansion and development of the system.

In 1847 the State University had been founded, and in 1868 the Agricultural College was opened. In 1849 the first permission to form higher grades in schools had been granted; in 1851 the first graded school had been organized; and in 1870 the County High School Law was passed. In 1868 the standards for certifying teachers were raised, and in 1882 a State Board of Examiners was created and

state teachers' certificates authorized. In 1876 women were made eligible to hold school offices, and in the same year the state normal school was established. In 1896 school corporations were authorized to provide free textbooks if permitted to do so by vote of the people. In 1882 Arbor Day was instituted. In 1906 a compulsory education law was enacted. In 1911 the consolidation of schools and the transportation of pupils, free high school tuition, and county teachers training classes were provided for.

**Present School System** — The school system of Iowa, as at present organized, is as follows. At the head is a State Superintendent of Public Instruction, elected by the people for two-year terms. He is charged with the duty of preparing and distributing courses of study for the rural and high schools of the state, of collecting and publishing certain kinds of statistical information, of preparing questions for the use of county teachers' examinations and grading the papers; of rendering opinions and determining appeals from the decisions of the county superintendents, of calling the county superintendents together in convention, of designating a time and place for holding county institutes and approving the conductors selected, and of making an annual report to the Auditor of State and a biennial report to the Governor. His salary is \$2200, with \$300 for traveling expenses. He is also *ex officio* a member of the State Educational Board of Examiners and president of the board, of the board of regents of the state university, of the board of trustees of the State College of Agriculture and Mechanical Arts, and of the board of trustees of the state normal school, and president of this board.

The State Educational Board of Examiners is the nearest approach to a State Board of Education that Iowa has had since the abolition of that board in 1864. It was established in 1882 to hold examinations for state teachers' certificates, and is composed of the State Superintendent of Public Instruction, the president of the state university, the principal of the state normal school, and two persons appointed by the Governor for four-year terms, one of whom must be a woman. They are charged with the duty of holding two examinations annually for state certificates and state diplomas, they may issue special certificates for special lines of work, and may validate certificates from other states if these have been issued on equivalent requirements. This board is also a board of inspection and supervision of schools for the training of teachers, approving institutions, and providing rules for the certification of graduates of the approved institutions. The board also makes out lists of books for which the library fund may be spent by the School Directors of the state.

For each county a county superintendent is elected by the people for two-year terms.

He is to serve as a means of communication between the State Superintendent and the township or district school authorities, must visit the schools of the county, must hold four examinations for county teachers' certificates each year, using questions prepared by the State Superintendent, and transmit the answer papers, with his opinions and impressions, to the State Superintendent for grading, may conduct a special examination with the permission of the State Examination Board, if there should prove to be a shortage of teachers for the county; must conduct an annual county teachers' institute, must see that all school laws are enforced, and must make an annual report to the Superintendent of Public Instruction. To qualify for the office, a county superintendent must hold a first-grade county teachers' certificate, a state teachers' certificate, or a life diploma. The salary is \$1250 a year for all counties. There also exists in each county a rudimentary type of a county board of education, consisting of the county superintendent, the county auditor, and the county board of supervisors. The duty of this county board seems to be only to submit the question of county uniformity in school textbooks to the voters of the county, when petitioned to do so by one third of the school directors of the county, and to adopt uniform textbooks for the county in case the voters decide that they want county uniformity.

Aside from a certain centralized control over teachers' institutes, and the examination of teachers, Iowa may be said to represent a decentralized system, somewhat analogous to that of certain New England states, as the greatest power and authority is in the hands of the township and district school corporations. Each congressional township was created a school township by the law of 1858, but since then great numbers of independent districts have been organized. While the township is nominally the unit of organization, with subdistricts, as a matter of fact, any city, town, or village having 100 residents, and any rural subdistrict may be set off as independent school districts, having their own board of school directors, escaping township taxes, and managing their own affairs, subject only to the control of the county and state superintendents, as enumerated above. This is the weakest feature of the Iowa school system. Subdistricts and townships hold annual school meetings. Women are eligible for school offices, and may vote on all questions relating to taxes and the voting of bonds. Subdistrict annual meetings have the power to elect a member of the board of school directors, and to vote extra subdistrict taxes for maintenance or for schoolhouse purposes. The township annual meeting has power to direct a change of textbooks; to provide for free textbooks; to add to the branches of instruction; to sell, lease, or let school property, to authorize the

construction of roads to the schoolhouses; and to vote bonds and a schoolhouse tax up to ten mills. Township boards are required to take an annual school census in June, to notify the county superintendent when the schools are to begin; to determine the amount of the teachers' and contingent fund necessary, and to notify the county board of supervisors, whose duty it is to levy it, to prescribe the course of study for the schools, to care for the school property, locate schoolhouses, determine what schools pupils may attend and fix the length of term; to carry into effect the legal instructions of the annual school meeting, to elect teachers and dismiss them for cause; to designate school visitors from among their own number; and to make an annual financial report to the annual meeting and to the county superintendent. Boards of directors may also contract with other corporations to teach children if more convenient, or may furnish transportation, if cheaper, either within or without the township; may establish graded union or high schools, of their own volition, may establish kindergartens and employ a township superintendent, may petition the county superintendent for a vote on county uniformity and free textbooks, may authorize each director to furnish fuel, supplies, and a teacher for his subdistrict; must expend between five and fifteen cents per pupil for the school library each year, and may expend up to \$25 per school per year for library and apparatus; may appoint a truant officer, may contract for all the textbooks used in the schools and buy and sell them to the pupils at cost, furnishing free books to indigents, or they may furnish them free to all pupils and pay the expense out of the township contingent fund, if so directed by the annual school meeting. The treasurer of the board of directors receives all money due the township or district and pays the same out on the order of the president and secretary of the board.

**School Support.** — At the time of its admission into the Union, Iowa received the sixteenth section in each township, or a total of 905,134 acres from the government, for the benefit of common schools. The 500,000 acres of land granted to new states, some saline lands, 5 per cent of the sale of United States lands within the state (after 1857), and the net proceeds of the estates of persons dying without will or heir have been added to the permanent fund. The lands have all been sold, and a fund of about four and three quarter millions has been produced. The income on this was \$214,132 30 in 1905, and remains nearly constant from year to year. This is equal to about thirty cents per census child, five to twenty-one years of age, and is distributed to the counties by the State Auditor on this basis. No state school tax is levied or appropriated. The only state grant for education, aside from the appropriations for the support of the higher educational

institutions, is a grant of \$50 per county each year for the benefit of county institutes.

In each county a county school tax of not less than one nor more than three mills must be levied for schools, and the proceeds of this tax together with the income from the state school fund and the net proceeds of all fines collected for breaches of the penal laws, is distributed by the county auditor to the different school corporations of the county wholly on the basis of the school census. Each school corporation raises the balance of the money needed to maintain its schools by local taxation. When a district or town withdraws from the township organization and sets up an independent district, this action renders void any tax previously levied on the new independent district. The result of this is to effectually prevent any equalization of school burdens, as the wealthier subdistricts can escape all general taxation except the county tax. The local tax for contingent funds is limited to \$5 per census child and not over \$75 per school, and the local tax for teachers' salary fund is likewise limited to \$15 per census child or \$175 per school. Low teachers' wages are the result of such limitations.

**Educational Conditions** — The state is essentially rural and agricultural, and the large number of small schools which must be maintained is probably the cause of the low expenditure. Of the total population about 75 per cent live in country districts, and only about 16 per cent lived in the seventeen cities of over 8000 inhabitants. Of the total population 99.4 per cent are white, and about 85 per cent are native born. The foreign-born are chiefly Germans, Scandinavians, and English. The state consequently has no negro problem or foreign problem to deal with. The percentage of illiterates in the total population, ten years of age or over, was but 2.3 per cent, which, with Nebraska, was the lowest of any state in the Union. The compulsory attendance law requires that all children between seven and fourteen must attend school for sixteen weeks if physically and mentally capable and if living within two miles of a schoolhouse. Private and parochial schools must make attendance reports. Any school corporation may appoint a truant officer, but the means provided for enforcing the law are not such as to ensure any adequate enforcement.

In addition to the regular elementary school instruction, a number of counties provide some instruction in agriculture; about thirty cities and towns maintain kindergartens, a rapidly increasing number report instruction in manual training; and in domestic science. School libraries exist in all schools, and each school corporation must devote from five to fifteen cents per census child to the purchase of books for the school library. The law provides that the Bible shall not be excluded from the schools of the state, or from any state in-

## IOWA COLLEGE

stitution, and readings from the Bible with a repetition of the Lord's Prayer by the teacher and school is authorized.

**Teachers and Training.** — The state maintains one large and well-organized normal school for the professional training of teachers, which has a little over 200 graduates annually. In addition to the state normal school, a number of colleges assist the state in the preparation of teachers, being accredited for this purpose by the State Educational Board of Examiners, which is authorized to inspect and accredit such institutions, and to determine the conditions under which the graduates of these institutions may receive teachers' certificates. Normal training classes in high schools were authorized in 1911, and in time they will add materially to the number of trained teachers in the state. All teachers' certificates are issued by the state.

**Secondary and Higher Education** — Graded schools and high schools are to be found in all the cities and larger towns, and also in many of the independent districts and consolidated townships. The state is well supplied with high schools. No state or county aid is given to them, each being maintained by local taxation. Although provision exists in the law for forming county high schools, few have been formed, and the law has not been regarded as successful.

The University of Iowa (*qv*) at Iowa City, opened in 1855, and the Iowa State Agricultural College (*qv*) at Ames, opened in 1868, form the culmination of the public school system of the state. The state also maintains the Iowa Industrial (reformatory) School for Boys at Eldora; the Girls' Industrial (reformatory) School at Mitchellville, the Iowa College for the Blind at Vinton, the Iowa School for the Deaf at Council Bluffs, and the Iowa Institute for Feeble-Minded Children at Glenwood. **IOWA STATE COLLEGE, AMES, IA.** — An agricultural and mechanical arts college for men and women founded by act of the state legislature in 1858. In the following year a

## IOWA WESLEYAN UNIVERSITY

farm of 640 acres was purchased for the use of the college. In 1862 the General Assembly accepted the land grant offered by Congress for the establishment of agricultural and mechanical arts colleges. By a state act of 1882 provision was made for giving a necessary liberal education in addition to the purely specialized courses. The entrance requirements are fifteen units. The college offers four five-year courses in engineering and fourteen four-year courses in engineering, the different branches of agriculture, veterinary medicine, general science, and home economics, all leading to degrees. The faculty consists of eighty-eight professors; there are eighty-four instructors and assistants. In 1911, 2307 students were enrolled in different courses, including short winter courses and music.

**IOWA STATE UNIVERSITY, IOWA CITY, IA** — A coeducational institution forming an integral part of the public educational system of the state. An act establishing the university in Iowa City was passed in 1847, but the opening was postponed until 1855. Until 1860 only a normal department was maintained. Subsequently the following departments, now colleges, were added: law (1868), medicine (1870), homœopathic medicine (1876), dentistry (1882), pharmacy (1885), graduate (1905), applied science (1905). Since 1909 the university, together with the State Teachers' College and the State College of Agriculture and Mechanical Arts, is under the control of the State Board of Education. The university plant consists of thirty buildings on a campus of fifty acres. The income is derived from invested funds and state appropriations. The university was among the first to organize university extension courses in different parts of the state, a movement which has met with success. Students are admitted on satisfying the entrance requirements of fifteen units. The usual university degrees are granted by the institution. The total enrollment in all departments in 1909-1910, including summer session, was 2352. The faculty consists of sixty-nine members of professorial rank and 150 instructors of other grades.

**IOWA WESLEYAN UNIVERSITY, MT. PLEASANT, IA** — A coeducational institution founded in 1842 as the Mt Pleasant Collegiate Institute; the present title was adopted in 1854. It is under the auspices of the Methodist Episcopal Church. The university maintains an academy, college of liberal arts, normal, music, and commercial departments. The entrance requirements are fifteen units. The college, on the completion

of appropriate courses, grants the degrees of A B., B S., and Ph B. There is a faculty of twenty-eight members.

**IRELAND, EDUCATION IN. — Early History.** — *Under the Druids.* — In the most valuable information given by Cæsar about the druids (see DRUIDS, SCHOOLS OF THE) there is much which may be almost certainly transferred to the earliest teachers and schools of Ireland. The Irish term for a druid was *drui*, modern *draoi* (*dhree*), but its genitive is *druid*, from whence no doubt the Latin *druidis*. The Irish druids were the learned class in early Ireland, as they were in Gaul. They were the lawyers, poets, astronomers, and instructors of youth, and are intimately connected with all early Irish history and fiction.

The invading Milesians had, according to Irish legend, three druids with them in their ships, one of them the poet Amergin. They continue to be frequently mentioned, down to the times of the early Irish Saints. They are met with not only as teachers or tutors, but also as ambassadors and spokesmen. Kings were sometimes druids; so were poets. The word, indeed, seems to have been used with much laxity in early Ireland, and they do not seem there to have formed a definitely established order or caste, still less a regular sacrificial priesthood, as they did upon the Continent, nor does there appear anything to connect them in any way with human sacrifice. In the Latin lives of the Saints the word *druid* is generally translated by *magus*. Some of the early saints appear to have lived on fair terms with them.

When the druid died out as a druid is doubtful; the word evidently had an evil sound in the ears of the early Christians, and, while much of the druids' teaching and school organization must have been quietly perpetuated, they themselves either disappeared or else silently adapted themselves to the changes introduced by Christianity. The doctrine of metempsychosis, which was so vigorously insisted upon in Gaul (*cf* Cæsar *de Bello Gallico*, VI, 14) was perfectly familiar to the early Irish, as saga after saga shows us, though there is nothing to prove that the Irish druids elevated it into a doctrine to be taught in the schools with the deliberate ethical purpose of making men valiant. Again the early books of the Brehon law (and the druids appear to have been the first brehons or judges) contain many curious teachings about the heavenly bodies, the colors of the various winds, and the like, things about which, as Cæsar tells us, the Gaulish druids taught also. There are many other indications that the Gaulish and the Irish druids had much in common, as the chief teachers of their respective nations.

*Schools of the Bards and Brehons.* — With the gradual abolition of paganism in Ireland the druidic name seems to have died out, and

their place to have been taken by the bards and brehons, who were probably their direct, gradually christianized, successors. We know that, side by side with the colleges of the early clergy, there flourished, perhaps in a more informal way, the purely Irish schools of the bards and brehons, but though, thanks to the very numerous lives of early saints, a great deal is known about the Christian colleges, little can be discovered with certainty about the bardic institutions, which represented something much more antique than even the very earliest schools of the Christians. Unlike the Christian schools, however, they do not seem until the end of the sixth century to have been centered in a fixed locality or in a cluster of houses, but to have been peripatetic. The bardic scholars appear to have grouped themselves rather round personalities than localities and to have wandered freely over the entire country, gladly supported by the people. From what must have originally been the druidic school we can see gradually emerging the poet, the brehon, and the historian. At first a poet was by virtue of his office a judge, and there is an interesting account of how through their predilection for technical language which none but themselves could understand they lost this privilege in Conor MacNessan's time, shortly before the Christian era (*Irische Texte*, III, B, 1, pp 187–204). But we lack exact data to show how and when the historian, the poet, and the brehon differentiated themselves from the more primitive druid. The brehon and historian were frequently united in the same person, for where the lawgiver's judgments concerned, as they so frequently did, the holding of tribal land by virtue of descent, it was almost necessary for him to be a tribal historian as well as a lawgiver; and as much of both tribal genealogy and law was enshrined in verse, he had to know something about this as well. The poets, however, were not necessarily historians or judges. They were a class in themselves, and they were at one time so numerous and so insolent that they constituted an intolerable burden upon the country. Three separate attempts (Keating's *History*, and MacFirbis's *Genealogies*) were made to get rid of them; but each time they found refuge in the northern province of Ulster. At length at the end of the sixth century, a period when, according to the Irish historian Keating (*History*, O'Mahony's translation, p 446), nearly one third of the free tribes or patrician families had embraced poetry as a pursuit, a determined effort was made by King Aedh MacAmmirech to shake off their incubus. He held a great convention of all Ireland at Drum Ceat, near Limavaddy, in the north of Ireland, to discuss several matters of importance, not the least of which was the banishment of the poets.

It was the intervention of St. Columcille, a poet himself, who saved the bardic institution

from extinction or banishment on this occasion. The numbers, however, were cut down to a mere tithe of what they had been. The High King, the kings of the provinces, the chiefs of each territory, and the lords of each subdistrict were all allowed to keep their own Ollamh (*ollav*) or chief poet. None, except those specially sanctioned, were to be allowed to pursue a bardic calling. On the other hand, the order was compensated for this in another way. Their unchartered freedom and licentious wanderings were checked, but they now became for the first time possessors of fixed property and of local stability. Distinct public estates in land were set aside for their maintenance, and they were obliged in return to give public instruction to all comers in the learning of the day. Rathkenry in Meath and Masree in Cavan are particularly mentioned as bardic colleges then founded, where any of the youth of Ireland could acquire a knowledge of history and the sciences. The High King, the provincial kings, and the sub-kings were all obliged (MacFibris Ms., *Book of Genealogies*, Preface) by law to set apart a certain portion of land for the poet of the territory to be held by him free of rent, and a law was passed making the persons and property of the poets sacred. At the same time the amount of rewards which they were allowed to receive for their poems was legally settled. From this time forward, for nearly 1000 years, the bardic colleges, as distinct from the ecclesiastical, taught poetry, law, and history, and educated the lawyers, judges, and poets of Ireland.

There were two kinds of poets, the *file* (*filla*) and the bard, the first being the most important. The legal price of his poems was much greater than that of the bard. There were seven grades of *file*, differently named and of different dignity. In his first year the *file* had to learn fifty Ogams, and straight Ogams amongst them. He had to learn the grammar, called *uraicept na n-éigisne*, with its preface, and that part of the book called *reimeanna*, or courses, with twenty *dréachts* (story-lays?), six meters, and other things. The original course of study seems to have been taken in seven grades, but afterwards it lasted for at least twelve years or more (O'Curry *Ms Materials*, p. 290). Compare with this Cæsar's statement about some of the Druids' pupils continuing their study for twenty years. The highest poet was called an Ollamh (*ollav*) and the annalists give the obituaries of the arch-ollamhs as if they were so many princes. When a poet had at last, after twelve or twenty years of study, worked himself up through all the lower degrees and had attained the rank of an Ollamh, his knowledge, amongst other things, included the following. He knew three hundred and fifty different kinds of versification, he was able to recite and coordinate two hundred and fifty Prime Stories and one

hundred Secondary ones. The ancient and fragmentary *Miss (Irish Texts, III, Heft 1)* in which these details are preserved not only give the names of the meters which the poet had to know, but have actually preserved examples of between two and three hundred of them, taken from different ancient poems, almost all of which have long since perished. Nearly all the textbooks used in the career of the old Irish poet during his twelve years' course are lost, and with them have gone the particulars of one of the most unique and interesting civilizations in Europe. The bards, who were not nearly so important as the *files* were divided into two great classes, the Saor and Daor, or patrician and plebeian bards. There were eight grades in each class, each having a title and honor of his own. Each of these sixteen classes had his own peculiar meters, and the lower bard was not allowed to encroach upon the meters sacred to the bard next in rank. The elaborateness of the system they evolved, the prodigious complexity of the rules, the subtlety and intricacy of their poetical code are astounding, as was also the number of people who followed the profession of poet.

It was not until the Northmen (who first invaded the peaceful shores of Ireland at the close of the eighth century) had laid waste the country and thrown everything into the wildest confusion, that the distinction between the *bard* and the *file* was lost.

**The Great Christian Schools** -- St. Patrick (died 493?) and the early Christians of the fifth century spent most of their labor upon the conversion of pagans and the building of churches. Columcille (521-597) and the leading churchmen of the sixth century had leisure to give themselves up to the foundation of monastic institutions and the conduct of schools. By the middle of this century Ireland found itself dotted all over with schools, monasteries, colleges, and other foundations belonging to the Christian community, and books had already multiplied to a marvelous extent. The three patron Saints of Ireland, Patrick, Bridget, and Columcille had established their schools at Armagh, Kildare, and Iona. After them St. Edna, whom Dr. Healey (*Ireland's Ancient Schools and Scholars*, p. 164) calls one of the fathers of monastic life in Ireland, settled down finally about the year 483 on the rocky and nearly inaccessible Island of Aran Mór, and he was the first of the holy men who won for it the appellation of Aran of the Saints. Here he was visited by many other celebrated men, among them by Brendan the Voyager, whose wanderings, under the title of *Navigatio Brendani*, became so celebrated later on throughout medieval Europe. To him came St. Finnian, of Clonard, known later as the "Tutor of the Saints of Erin," Finnian of Moville, Ciaran of Clonmacnois, Jarlath of Tuam, and Carthach of Lismore. It is said that even St. Columcille himself in his youth

sought Aran to hold converse with him. St. Finnian's school at Clonard, hard by the river Boyne, was founded about the year 520, and even during his own lifetime became a great institution, and three thousand students are said to have gathered round it. It continued to grow in wealth and dignity until the ninth century, but after that time Ireland was in the throes of the Norse invasion, and it was plundered and destroyed twelve times, and burnt down wholly or in part no less than fourteen times. Clonfert on the Shannon was another great college, founded by Brendan the Navigator, and it is said to have produced three thousand monks. Fursa, whose visions were known all over Ireland, Britain, and France, and no doubt (through Bede's *History*) to Dante, was a grand nephew and pupil of Brendan. Even a greater school than Clonfert was that founded by St. Ciaran, the carpenter's son, about the year 544 at Clonmacnois, at a curve in the Shannon near Athlone. This college was resorted to impartially by all the various tribes of Ireland, and the most divergent races both from the North and South gave it assistance and buried their dead in its shade, so that it became the greatest university in Ireland, and produced some of the most distinguished scholars. But, like every other home of Irish civilization, it fell a prey to the barbarians. The Northmen plundered it or burnt it, or both, on ten separate occasions. Bangor on Belfast Lough founded by Comgall, the friend of Columcille, between 550 and 560, was, after Armagh, the greatest school in the northern province, "a noble institution," said St. Bernard (*Life of St. Malachy*). Columbanus, who evangelized large portions of Burgundy and Lombardy, St. Gall, the evangelizer of Switzerland, and Dungal, the astronomer, were all disciples of this college. St. Bernard says that the northern pirates slew as many as nine hundred of the inhabitants of Bangor. Other great institutions were Moville at the head of Strangford Lough in the County Down, founded by St. Finnian, who was born some time before A.D. 500, Clonenagh in Queen's County, founded by St. Fintan, Glendalough, founded by St. Kevin, Lismore, the great college of southeast Ireland, founded by St. Carthach, Cork College, founded by St. Finnbar, the school of Ross in Southwest Munster, founded by St. Fachtna, Innisfallen, founded upon an exquisite site on the lower lake of Killarney by St. Finan, and Iniscailtra, on an island in Lough Derg, founded by Columba of Terryglass, who died in 552. In addition to these, a great number of lesser schools existed, and they were crowded with students not only from Ireland, but from foreign lands. Bede tells us of the crowds of Anglo-Saxons who flocked over into Ireland during the plague about the year 664, and how they were all warmly welcomed by the Irish, who took care that they should be provided with food every

day without payment on their part, that they should have books to read, and that they should receive gratuitous instruction from Irish masters. Aldhelm, abbot of Malmesbury (a corruption of Mael-dubh's-bury, Maeldubh, its founder, having been an Irishman), tells us that, while the great school at Canterbury was by no means overcrowded, the English swarmed to the Irish schools like bees. The office of St. Cathaldus states that the school of Lismore was visited by Gauls, Angles, Scotti, Teutons, and scholars from other neighboring nations. The same was true of Clonmacnois and other foundations.

The original design of the founders of these schools may have been the propagation of the Christian religion, but it is certain that almost from the very first they taught the heathen classics and the Irish language side by side with scriptural and theological studies. All the knowledge of the time appears to have been taught through the medium of the Irish language, not merely theology but arithmetic, rhetoric, poetry, hagiography, natural science as then understood, grammar, chronology, astronomy, Greek, and even Hebrew. "In Ireland," sums up M. Darmesteter (*English Studies*), "the Classic tradition to all appearances dead in Europe burst into full flower." "The Renaissance began in Ireland seven hundred years before it was known in Italy", and again "at one time Armagh, the religious capital of Christian Ireland, was the metropolis of civilization." "In the next (sixth) century," says Babington (*Fallacies of Race Theories*, p. 122), the old culture lands had to turn for some little light and teaching to that remote and lately barbarous land (of Ireland)."

The Greek language, all knowledge of which may be said to have died out on the Continent ("had elsewhere absolutely vanished" says M. Darmesteter), was widely studied in Ireland. There is a Greek *Ms* of the Psalter, written in Sedulius's own hand (he was Abbot of Kildare about 820), now preserved in Paris, and at least a dozen other Greek texts written by Irish monks are preserved elsewhere in Europe. The knowledge of Greek, says Professor Sandys, in his *History of Classical Scholarship*, "which had almost vanished in the West was so widely dispersed in the schools of Ireland that if any one knew Greek, it was assumed that he must have come from that country."

*Irish Teachers on the Continent* — From about 600 to 850 A.D. was the most barbarous and the darkest period of the Middle Ages upon the Continent, a period when all study, both classical and ecclesiastical, was at its very lowest ebb. It was at this period, especially toward its close, that the Irish nation, by general acclamation the most cultured in Europe, sent forth the swarms of scholars to the Continent to teach and preach and found monasteries and preside over schools. About

the year 800 Cambrai was a celebrated rallying place of theirs "Not only Cambrai," says M. Dom Louis Gougaud (*Les Chrétiennes celtiques*, p. 289), "but also Rheims, Soissons, Laon, and Liège, had at one and the same period colonies of Irishmen" At Laon, indeed, thanks to the efforts of the erudite Hibernians, it became for a while the fashion to dabble in Greek "Bishop Hincmar tried it, and more, he who did not know his own language — according to his uncle Hincmar of Rheims — prided himself upon learning to speak in Irish" (*Hincmar opusculum LV Capitulum*, quoted by Gougaud) "If," says M. Gougaud, "we consult the evidence given by their contemporaries concerning the learned men that had come amongst them out of Ireland, we must acknowledge that they all show that they are conscious of being greatly in their debt for the progress realized in their studies. Irish knowledge is in their eyes something apart from all else, and worthy of their most pompous encomiums" (p. 293)

But with the evil days of the Vikings came change. The ancient monasteries, shrines, schools, and colleges, and all settled institutions of society offered to the fierce Norsemen the first objects of onslaught, and the shrines of the churches, above all, promised them plunder. For two centuries they made, to quote the words of the almost contemporary Irish historian, "spoil-land and sword-land and conquered land of her, ravaged her chieftainries and her privileged Churches and her sanctuaries, and they rent her shrines and her reliquaries and her books, and demolished her beautiful ornamented temples — in a word, although there were an hundred sharp, ready, cool, and never-rusting brazen tongues in each head and an hundred garrulous loud unceasing voices from each tongue, they could never relate or enumerate all the Gael suffered in common, both men and women, laity and clergy, noble and ignoble, from these valiant wrathful purely-pagan people" (*Wars of the Gael and Gall*, p. 51). One aim of the Norsemen was to destroy all learning. "It was not allowed," writes Keating, "to give instruction in letters . . . No scholars, no clerics, no books, no holy relics were left in Church or monastery, through dread of them. Neither bard nor philosopher nor musician pursued his wonted profession in the land" (Keating's *History*).

On the afternoon of Good Friday, Apr. 13, in the year of our Lord 1014, the dream of a Scandinavian kingdom in Ireland was shattered forever by the crushing defeat of Clontarf, where, however, fell the King of Ireland, his son and heir, and his son's son and heir, leaving the monarchy greatly imperiled and the High-Kingship thrown open, as it were, to competition — to any one who was powerful enough to wrest it to himself. Nevertheless the succeeding century and a half witnessed a great revival of art and learning, of schools

and scholarships. The books "drowned" by the Northmen were rewritten in the language of the period, the churches and monasteries rebuilt, the schools repeople, the bards and brehons reinstated, and some of the old civilized polity brought back. Even before the battle of Clontarf, King Brian had sent emissaries "to buy books beyond the sea and the great ocean," because, says the history, "their writings and their books in every church and in every sanctuary where they were had been burnt and thrown into water by the plunderers" (*Wars of the Gael and Gall*). It is from the brief period of comparative rest succeeding the battle of Clontarf that the most important relics of Celtic literature now in the world date.

The Irish still continued, however, to travel and preach. In 1076 they founded the great monastery of Ratisbon. That of St. James they completed in 1111. They are now to be found as far afield as Bulgaria and Poland. They founded the Monastery of Wurzburg in 1134, Nuremberg in 1140, Constanze in 1142, St. George in Vienna, in 1155, Eichstadt in 1183, St. Maria in Vienna in 1200, and scores of others.

*The Norman Invasion and Irish Learning.* — One hundred and fifty-five years after the battle of Clontarf, that is to say, in May, 1159, appeared the first Norman invaders, and these repeated, though perhaps in a milder form, the havoc and plunder of the Northmen. By the close of the century they had established themselves over Ireland. Then commenced that permanent warfare between the English and the Irish which rendered all literary scholastic and artistic advancement practically impossible. Ireland became, to use a graphic expression of the Four Masters, a "trembling sod." "Since the Norman invasion," wrote the late Miss Stokes, the highest authority upon this subject, "the native character of Ireland has best found expression in her music. No work of purely Celtic Art, whether in illumination of the sacred writings or in gold or bronze or stone was wrought by Irish hands after that century."

The exact position of learning and of education during the four centuries which follow are very obscure. The Normans almost invariably attacked church and monastic property, as being generally the least vigorously defended. They deliberately quenched the holy fire which had burned unceasingly in the shrine of St. Bridget from the fifth century onward,

"The Lamp which once shone in Kildare's holy fane  
And burnt through long ages of darkness and storm,"

and generally set themselves from the first against native Irish institutions, monasteries, schools, and colleges, both in church and state. They established churches and sanctuaries of their own, and to these institutions no native Irishman was to be admitted. Gradually, however, the bulk of the Normans became

largely assimilated with the Irish. They soon gave up talking Norman-French, and spoke and wrote only in Irish. The schools of the bards and brehons which existed throughout the island supplied them, as they did the Gaels, with their family poets, and as most of them adhered to the Brehon law as proper and more suitable to their surroundings than the English, they no doubt were dependent largely upon the Irish schools for their judges and historians also. In most or all of these schools, Latin was spoken as a second language. Every one of any education at all in Ireland spoke it fluently, and through it the Irish, cut off from England by the perennial war between the two nations, kept in the closest touch with the Continent. "They speak Latin like a vulgar language learned in their schools of Leachcraft and Law whereat they begin children and holde on sixtene or twentie yeares," wrote Campion in 1574. "I have no doubt," writes the Right Hon. Mr. Justice Madden in his book on the *Classical Learning in Ireland* (Dublin, 1908, p. 43), "that the use of Latin as a written and spoken language outside the Pale is a survival from the centuries during which Ireland was the University of Western Europe."

*Irish Schools under Elizabeth and her Successors* — Elizabeth's wars did much to break up the power of the native Irish and with them their schools and institutions. Their monasteries had, whenever the English could get at them, been already secularized by her father, Henry VIII, and the collegiate establishments connected with them broken up.

It was the deliberate policy of the English to destroy all the schools and institutions of the native Irish and to kill or banish their learned men, especially the poets. In the Pale, however, and in those parts of Ireland where the English plantation held there were some good grammar schools conducted on English lines which were not interfered with, and some of their best scholars went on to Oxford or Cambridge, generally Oxford. At one time great numbers of native Irish went there, too, but they were soon prohibited by law from availing themselves of this means of education, as Mrs. Green has shown in her *Making of Ireland and its Undoing*. The most ferocious laws of all were passed against the unfortunate poets, and many of them were hanged. James I followed the same policy. Under him the native schools seem to have been ruthlessly closed by Ussher, who became, later on, the Protestant Primate, on the convenient ground that the teachers did not conform to the established religion. Yet some of the bardic schools and of those of the brehons continued surreptitiously to exist, though in ever decreasing numbers and with diminishing prestige, until the first quarter of the seventeenth century. When the Confederate Irish rose to arms in 1642, they strove to reestablish their

native schools, and we find Rory O'More, the close friend of Owen Roe O'Neill, writing to Brussels and urging that the "learned and religious fathers" at Louvain should hasten over to Ireland with their Irish printing presses so as to open an Irish school "before Flan MacEgan dies." This MacEgan was an eminent brehon and head of a celebrated school of law and history in Lower Ormond at the time. The sword of Cromwell, however, put an end to this dream.

The bardic school, to follow the description of them given in the *Memoirs of Clanrickard*, printed in London, 1722, was usually a group of low whitewashed buildings lying in the hollow of a secluded valley or shut in by a thick, sheltering wood, far removed from human traffic and the noise and bustle of the great world. It had few apertures. Each student as he arrived was assigned a windowless room to himself with no other furniture than a couple of chairs, a clothes rail, and a bed. Those students who did not know all about the intricacies of the Irish metrical system, its syllabification, quartans, concord, correspondence, termination, union, laws of nudation, etc., were turned over to the inferior professors. After breakfast the students, having been allotted a theme, returned each to his warm but perfectly dark compartment to throw themselves each upon his bed, to think or compose until supper hour, when a servant came round with candles for each to write down what he had composed. They were then called together into the great hall and handed their written compositions to the professors, and chatted and amused themselves till bedtime. The schools always broke up on the 25th of March, and the holidays lasted for six months. Only members of bardic families as a rule were admitted to the bardic schools, and poetry as a profession ran very largely in special clans, thus tending from the fourteenth to the seventeenth century to become in a way hereditary. The O'Dalys were perhaps the principal poetic family of Ireland, but there were over a score of other families who followed poetry as a profession or from hereditary instinct, as the O'Clearys, O'CoFFEys, O'Higgins, Wards, etc.

Elizabeth having extirpated, so far as her power extended, both bards and brehons, and broken up the native Irish schools, set about giving the Anglo-Irish, the planters, and Protestants a university of their own in Dublin. To do this, she founded Trinity College, which has now flourished as a great seat of learning for over three hundred years, supported, however, largely by the lands plundered by the Queen from native Irish institutions. (See DUBLIN UNIVERSITY.) James I and his successor followed this up by founding a number of "Royal Schools," evidently intended as feeders to the new college, — Portora, Enniskillen in 1618, Armagh and Dungannon in 1627, and others. Peter Lombard, the Catho-

the Archbishop of Armagh, who died in 1625, describes in his *Commentary on the Kingdom of Ireland*, published on the Continent, in Latin, how it had been the steady policy of the English government to cut off all education from the native Irish, even before the difference in religion brought about by the Reformation gave them an additional excuse for doing so. And when the University, so long and so anxiously sought for by the natives, was at last founded *sumptibus indigenarum*, at the expense of the native inhabitants, "most capacious, most splendid," in the shape of Trinity College, Dublin, and they saw themselves excluded from it nominally on religious grounds, their indignation knew no bounds. But indignation availed them little. When they backed it with their swords, Cromwell beat them, and their last state was rendered worse than their former one.

The Restoration and the short-lived rule of James II did not avail very much to reinstate Irish learning or Irish schools. The period was too short and the times too troublous. Then came the defeats at the Boyne and Aughrim and the treaty of Limerick in 1691. After this, all hopes were shattered. The era of the Penal Laws against Catholics commenced, and as almost all the native Irish were Catholics, they were practically deprived of all education. Henceforth, so far as the education of the native Irish, who were the vast bulk of the Irish population, is concerned, it is as an organized thing nonexistent, picked up furtively at home or illegally acquired abroad. Stories are told of children deprived of books learning their letters on their fathers' tombstones. The possession of an Irish Ms might easily involve the owner in serious trouble or send him to prison. Many valuable books were buried or built up in walls. It was in a wall that the great valuable old Irish Ms, the *Book of Lismore*, was found during the last century. There were no native schools any longer existing except those of the kind later known as Hedge-schools (*q.v.*), where in fine weather the children assembled under the hedges. Still, despite indescribable educational hardships and privations, the classical tradition did not wholly die out. Crofton Croker (*Researches in the South of Ireland*) at the beginning of the last century mentions that "among the peasantry classical learning is not uncommon, and a tattered Ovid or Vergil may be found even in the hands of common labourers." For an account of these hedge-schools in later times, Crofton Croker and Carleton may be consulted. But, to sum up briefly, from the period of the battle of the Boyne down to about the year 1790, when Catholics were at last admitted to matriculate in Trinity College, though allowed none of its honors or emoluments, the words "education" and "Ireland," with regard to schools, colleges, or institutions, have no connection, except in so far as they concern the Anglo-Irish and the Protestant population. D. H.

**Modern Period — Primary Education —** The cradle of Irish, and in a sense of English and Scotch, primary education, in the modern acceptance of the term, is to be found in a large school founded in Dublin in 1786. (For this school were built, in 1798, the premises used to this day by the West Dublin Model Schools.) Here was devised a monitorial system, similar to that afterwards connected with the names of Bell and Lancaster, and here took origin the principle of educating the poor without religious interference.

A quarter of a century later, in 1811, the success which had attended the experiment encouraged the formation, on a national scale, of the "Society for the Education of the Poor," better known as the "Kildare Place Society." They proposed to cover Ireland with schools, open to all, and interfering with the religion of none. Their fundamental principle was that the Bible, as common to all sections of Christians, should be read daily, but without note or comment. A commission on education appointed in 1806, in its final report published in 1812, indorsed the principles of the society, and, in 1815, Mr., afterwards Sir Robert, Peel, then Chief Secretary, considered that the recommendations of the commissioners could best be carried into operation by parliamentary grants to the Kildare Place Society. The work of these pioneers, affecting as it has done, in a marked degree, England and Scotland, and to some extent each of the colonies, deserves fuller recognition than it has yet received. Here only the barest outlines are possible. The whole machinery of education had to be called into existence *ab initio*. As has always been the case in Ireland, the demand for knowledge was keen, but the means for satisfying it were crude. It is computed that perhaps five thousand schools of all kinds existed, but so wretched were they commonly that the term "hedge-school" (*q.v.*) was invented to describe them. For the application of the remedy, the society went vigorously to work. At Kildare Place they founded a model school for the training of teachers, which won the admiration of all — (see MODEL SCHOOLS), they published a series of schoolbooks which was largely used not only in Ireland, but in England and Scotland, holding that without a library no school was complete, they issued at cheap rates a collection of works, instructive and entertaining, which had no rival at the time, and in consequence went all over the world; with the help of the sums voted by Parliament, which rose to upwards of £30,000 a year, building grants were made to encourage and supplement the exertions of the localities, with the result that substantial schoolhouses, built commonly in accordance with plans furnished by the society, sprang up everywhere. Finally, a careful system of inspection was planned, the prototype, in many of its features, of every subsequent system, and a staff of

inspectors trained for the purpose visited the schools all over Ireland.

The success which rewarded the society was signal: 150 masters and 60 mistresses left the Training School each year; the annual output of the "Cheap Publications" was 60,000, the society's schools, which numbered 8 in 1816, had risen to 1621 in 1831, pupils to the number of 137,639 were in attendance, the average per school being between 84 and 85. It is not surprising that, with such a record in view, distinguished visitors from other countries, expressed their admiration and approval in the strongest terms. Professor Pillans (*qv*), prominent for his work on behalf of Scotch education, was of opinion that the Kildare Place Schools were a hundred years ahead of those in Scotland. The Count de Lasteyrie, in a letter still extant, pronounced the model school the best in the world.

In 1831 the Kildare Place Society was succeeded by the National Board. The fall was the result of the strictness with which they enforced the rule which enjoined the reading of the Bible without note or comment. The rule was never popular, churchmen objected to the prohibition of definite catechetical teaching, Roman Catholics received with suspicion anything of the nature of joint religious instruction, in 1827 the Commission of Educational Inquiry reported against the rule, and in 1829 a select committee of the House of Commons recommended that Irish primary education should be intrusted to a board responsible to Parliament, whose principle should be combined literary and separate religious instruction. The National Board, whose constitution was framed in accordance with this recommendation, met with violent and protracted opposition. The Presbyterians were the first to move; quite satisfied themselves with the Kildare Place Society, they resented what they considered a slight to the Bible, and in particular they found fault with certain regulations for promoting combined instruction, which would force them into joint action with Roman Catholics. Churchmen were not long in following. The absence of distinctive teaching had seemed to them a blemish in the Kildare Place Society, the Society, however, had insisted on the reading of the Bible, but the National Board not only made no such demand, but was even disposed to exclude from "school hours" any time which might be devoted to its study. The result was an educational schism which lasted more than fifty years, and at times threatened the very existence of the Board. For the prosecution of the attack the Church Education Society was founded in 1839. By adding definite denominational teaching to the Bible reading of the Kildare Place Society, a new warmth of interest was evoked, and the income from voluntary sources rose as high as £45,000, — more than Kildare Place had enjoyed at the height of its pros-

perity. So numerous were their schools that, as late as the date of the Powis Commission in 1870, they were held to constitute a dangerous menace to the Board. The last to oppose were the Roman Catholics, satisfaction at the overthrow of Kildare Place made them disposed to welcome the National Board, for a time even the Christian Brothers placed their schools in connection. Roman Catholics, however, were not more favorable towards combined instruction than the other opponents, and when the Board early changed "combined literary" into "combined moral and literary" by introducing for all a book of *Scripture Extracts*, their suspicions were aroused, and they lost no opportunity of giving publicity to their objections; in particular, the Synod of Thurles in 1852 openly denounced the system of the Board.

As the result of these attacks, many modifications were introduced into the original constitution. Two call for mention here (1) Non-vested Schools, as distinct from Schools Vested in the Board, were permitted, — a concession by which the principle of combined instruction was virtually abandoned, because, in a non-vested school, religious instruction cannot be given, as of right, except by the denomination with which it is connected (2) A compulsory conscience clause was introduced whereby the teacher must send away during religious instruction pupils of differing beliefs. In consequence of these and other concessions, the Board, which began with an undenominationalism more marked than that of Kildare Place, became transformed into a denominational system with a conscience clause, and as such it has completely solved the religious problem in connection with primary education in Ireland.

The education given in national schools began on Kildare Place lines, and the books of the society were largely used. Gradually the Board prepared books of their own, and until lately no others were permitted. The teachers were paid by local contributions, by school fees, and by fixed salaries depending on their classification. In 1870 a modified system of payment by results was superadded. It had the usual effect of emphasizing the subjects or portions of subjects which brought fees, to the detriment of the rest. In 1900 the resulting system was abandoned, and a new method of paying the teachers was introduced. At this date the amounts contributed by the localities were insignificant, and school fees had been abolished by the act of 1892. For purposes of salary, three grades were introduced. Teachers, who formerly rose by examination, are now promoted from the lowest to the highest grade by seniority and merit; they are also awarded triennial increments for good service, and receive a pension which is arranged on a contributory basis, on retirement. The average incomes from state sources are as follows: —

## IRELAND

PRINCIPALS		ASSISTANTS	
Men	Women	Men	Women
£112	£90	£81	£68

In addition to the more ordinary branches, the curriculum includes singing, drawing, object lessons, physical drill, hand and eye training including kindergarten, elementary science, cookery, and laundry. Instruction in these subjects has been much developed since 1900, and the same is true of Irish, which is now taught in 3066 schools to 180,000 children, as compared with 105 schools and 1825 children in 1899. On the 31st of December, 1909, there were 8401 schools in operation in connection with the National Board. In the following table the progress of primary education is shown from the Census Reports:—

	PROPORTION PER CENT				
	1861	1871	1881	1891	1901
Read and Write .	41	49	59	71	79
Read only	20	17	16	11	7
Neither Read nor Write .	39	33	25	18	14

*Higher Grade Schools* — The board, owing to the inadequacy of the grants, has hitherto been unable to make satisfactory provision for the higher education of promising pupils. For the Roman Catholics, the Christian Brothers have done much to remedy this deficiency, for the Church of Ireland the scholarships of the Incorporated Society have discharged a similar office.

*The Training of Teachers* — As was seen above, the training of teachers in Ireland had attained to European celebrity under the Kildare Place Society. The National Board founded its college in Marlborough Street in 1833. Till 1883 it remained the only government college, being undenominational, it met with little support from churchmen or Roman Catholics. In 1883 the English system of denominational colleges was extended to Ireland, and specially favorable terms were granted in 1890 in order to place the new college on a level with Marlborough Street. There are now seven colleges, one of them being the old foundation of the Kildare Place Society, which, as the Church of Ireland Training College, became a government denominational college in 1884.

*Secondary or Intermediate Education.* — The position of secondary, or, as it is generally termed, Intermediate, Education, during the century previous to the Commission of 1885, may be estimated by means of a passage from the commissioner's *Third Report*. After draw-

## IRELAND

ing attention to the inadequacy of existing endowments, they say "the subsequent course of our enquiries has confirmed our belief that the provision for intermediate education in Ireland is wholly inadequate, and bears no just proportion to the provision for university and primary education." Unsatisfactory as the results were found to be where the resources were so slender, the common mismanagement of the endowments made matters still worse. In striving to account for the failure of the Royal Schools, whose endowments were the largest in Ireland, the commissioners were of opinion that a prime cause was to be found in the constitution of the supreme authority. In 1813, as the result of the Commission of 1788, the royal and other endowed schools, were placed under a newly formed board, entitled the Commissioners of Education in Ireland. The constitution of the board was such that the commissioners were not brought into contact with the schools, nor had they direct interest in or control over them. But whatever the contributory causes may have been, the deficiencies of the intermediate schools as a whole were marked. During the last twenty-five years, however, a decided change has taken place, the credit for which is largely due to the Educational Endowments Commission, 1885-1894, and to the Intermediate Education Board. The Royal Commissions reorganized the Commissioners of Education, and perfected schemes for the management of upwards of 200 endowments. In all they did they emphasized the importance of giving the localities a definite share in the control of the schools, and made provision for dealing with neglect or inefficiency. The Intermediate Board represents an attempt of government to subsidize secondary education. Founded in 1878, and endowed with £1,000,000 out of the Irish Church Surplus, its funds were increased by the local taxation (customs and excise) act of 1890, — a variable source of income against whose fluctuations they have recently been guaranteed by fixed sums included in the estimates. As originally constituted, the sole duty of the board was to hold examinations in centers all over Ireland, and to distribute its funds upon the results, the schools receiving fees for each pupil who passed, and the pupils being rewarded with exhibitions and prizes. In 1900, in accordance with the recommendations of a royal commission, this cast-iron system was modified, and extended powers were granted; in particular, provision was made (a) for introducing inspection, (b) for arranging with the newly formed Department of Agriculture for practical examinations in science, and (c) for the encouragement of specialization. While few defend the methods of examination, and the payment on individual results which are indorsed by the acts under which the board works, and while none can excuse the sluggishness with which the required

funds are supplied by Parliament, there can be no question as to the quickening power which the board has exercised. As an illustration, it may be mentioned that though inspection was approved in 1900, the appointment of inspectors had to be delayed till 1909 through lack of the necessary funds. The intermediate schools of Ireland fall under three main divisions: the old endowed schools which, for the most part, are in Protestant hands; schools founded and managed by the different Roman Catholic orders; and schools which are the result of private enterprise. In 1850 the income of fifty-four of the largest endowed schools was under £15,000, and in ninety towns with population of 2000 and upwards, there was no provision of any kind for secondary teaching. Since the establishment of the Intermediate Board, a sum which has averaged £50,000 has been distributed annually among the schools, in addition to the prizes and exhibitions whereby deserving pupils have been helped. How the work has grown, the following table will show:—

NUMBER OF STUDENTS WHO PRESENTED THEMSELVES FOR EXAMINATION

	Boys	Girls	TOTAL
1879	2143	521	2664
1890	5726	2042	7768
1910	7967	3933	11900

The examinations in 1910 were held at 988 centers, in 127 different localities.

*Technical and Commercial Education.*—As early as 1841 the demand for education with a definite practical end took shape in the establishment of an engineering school in connection with Trinity College, Dublin,—a step in which the Irish university gave the lead to both Oxford and Cambridge. In 1867 the Royal College of Science was founded with the specific object of giving instruction in science as applied to the industrial arts, especially mining, engineering, and agriculture. In 1900 a step of much importance and fruitful in results was taken in the establishment of the department of agriculture and of technical instruction. With the help of parliamentary grants of upwards of £180,000 annually the department has been able to make progress in many directions, and has taken a prominent part in the industrial revival of the twentieth century. In many parts of Ireland special industries have been promoted and helped, much attention has been bestowed upon the improvement of live stock, and, in particular, admirable work has been done in connection with agriculture. The aim has been to place within general reach good technical knowledge of all subjects relating to agriculture. Local schools have been set up, and classes conducted in the most remote districts; itinerant instructors

and field demonstrators have gone everywhere. With such kindred institutions as the Albert Agricultural College, Glasnevin, and the Munster Institute, the department has willingly cooperated, it has made full use of the machinery of the county councils, and has employed the College of Science in many practical ways. The college is now under the management of the department, and its splendid new buildings opened in July, 1911, are rich with promise. Specially worthy of notice is the educational work done in promoting practical instruction in experimental science, drawing, manual work, and domestic economy in secondary schools. Unlike the Intermediate Board, the department enjoys freedom of action, and has been able to plan its educational activities upon modern lines, with the most satisfactory results.

*Higher Education*—Trinity College, Dublin (see DUBLIN UNIVERSITY), and Maynooth were the universities of Ireland in 1800. Since 1794 Trinity had received students of all creeds, but Roman Catholics were debarred from its fellowships and scholarships. Maynooth had been founded by the Irish Parliament in 1795, with an endowment of £8000 a year, to prepare students for the Irish priesthood. From 1800 onwards the university question has passed through many phases, in all of which two sets of influences have been at work. The Roman Catholics, with fixed purpose, have been struggling to obtain for themselves a university which would combine unquestioned efficiency and due recognition of ecclesiastical authority. Trinity College, eager for the maintenance of its supremacy and independence, has either sought or accepted reform after reform, thereby demonstrating its liberality and enhancing its influence.

The steps taken toward satisfying the requirements of the Roman Catholics have been many. At the Union the endowment of Maynooth was continued. In 1813 it was raised to £8928. In 1815 the Maynooth Act gave a permanent subsidy of £26,000 a year, which was commuted in 1869 for a capital sum of £372,000 out of the Irish Church Surplus. Sir Robert Peel, who had shown a similar spirit in his recognition of the Kildare Place Society, was the first to take definite steps to meet the desire for a university which would be available for and acceptable to all. His plan was to found a group of federated non-sectarian colleges, affiliated for examinations and degrees with a central university. The Queen's Colleges, as they were called, were established and endowed in 1849 in Belfast, Cork, and Galway; they were given faculties in law, medicine, arts, and engineering. The establishment of the Queen's University in 1850 completed the scheme. From the first, anything of the nature of permanent success was hopeless. Before the plan was tried, its wholly secular character incurred the con-

denunciation of the Pope, and in the year of its foundation the university was denounced by the Synod of Thurles. Furthermore, the same year saw the Roman Catholics preparing to open a university for themselves. The result was the Catholic University of Dublin, which was founded in 1854, with Doctor, afterwards Cardinal, Newman, as its first rector. Perhaps the chief purpose served by this university was to emphasize the demand of the Roman Catholics for equality of treatment with reference to higher education. Refused a charter by the government, and therefore unable to grant degrees, depending wholly on private support, and for this reason compelled to work in a restricted area, the university could never satisfy the requirements. Very effectually, however, it drew the attention of statesmen alike to the earnestness and the determination of the Roman Catholic party, both clerical and lay, with the result that, for the rest of the century, and up to 1908, the question of a Catholic university was always prominent. After several previous attempts by other statesmen, Mr Gladstone (*qv*) introduced his bill in 1873. His plan was to have one great university, which would include different colleges, such as Trinity College, the Catholic University, and any other properly qualified. The project met with little favor, as provision was not made for endowing the Catholic College, the Roman Catholics were only lukewarm in their support, Trinity College, considering that anything which interfered with independence must be injurious, offered the most strenuous resistance. The bill was thrown out, and the ministry fell. Lord Beaconsfield was more successful when, in 1879, he abolished the Queen's University, and replaced it by the Royal University of Ireland. With the exception of its medical faculties, which required courses of lectures at certain recognized institutions, the new university was wholly an examining body which had power to bestow prizes, and confer degrees, on all who presented themselves, irrespective of their colleges. This alone was sufficient to include Roman Catholic colleges in university benefits, and the Catholic University of Dublin enjoyed some special advantages through being able to appoint on its staff fellows belonging to and paid by the Royal University. The effect was seen immediately in the reorganizing of the Catholic University. As a set-off to the Queen's Colleges, which would be credited as a whole with the distinctions of their students, six Roman Catholic colleges, viz. Maynooth, the Catholic University of Dublin, henceforth known as University College, University College, Blackrock, St. Patrick's College, Carlow, Holy Cross College, Clonliffe, and the Catholic University School of Medicine, were federated to form the Catholic University. The Royal University met with some favor, on account of its recognition

of the Roman Catholic colleges, there was, however, a feeling that the students of these colleges were at a disadvantage, as compared with those from the state endowed and equipped Queen's colleges, and it was strongly held that the whole scheme kept the Roman Catholic colleges in "tangible and humiliating inferiority to Trinity College, Dublin." In consequence, the agitation for equality of treatment continued. An attempt made by Mr. Bryce in 1906 failed, as Mr Gladstone had failed, because it proposed to interfere with the privileged independence of Trinity College. It remained for Mr Birrell to find what may perhaps prove a satisfactory solution of the difficulties in his Act of 1908. By this act two new universities were founded and endowed, viz the National University, and Queen's University, Belfast. The Royal University was dissolved, and University College, Dublin, Queen's College, Cork, and Queen's College, Galway, became constituent colleges of the new National University. Though the National University is undenominational, and free from tests, in awarding its honors and making its appointments, it encourages the teaching of religion, provided the expenses are not paid out of state funds, and its governing body is so constituted as to command the confidence of Roman Catholics. By way of endowment the National University received £170,000 for such expenses as buildings and equipment, together with an annual grant of £64,000. Queen's University, Belfast, received for building and equipment £60,000, with an annual grant of £18,000.

The Presbyterian Church has two colleges empowered to grant degrees in divinity, one in Belfast, the other in Londonderry.

The higher education of women has been promoted in particular by Alexander College, Dublin, the Queen's Institute, and the Ladies' College, Belfast. The Royal University stimulated the movement by being the first university in the United Kingdom to open its degrees to women.

**IRELAND, NATIONAL UNIVERSITY OF.** — See IRELAND, EDUCATION IN.

**IRENÆUS** (c 130-202) — Church Father, a pupil of Polycarp, who in his turn was a disciple of St. John, and is therefore a most important witness as to the life and faith of the Christian Church in the first two centuries of its history. In early life he removed from

Asia Minor to Rome, where he became influential as a teacher. In 177 he was made Bishop of Lyons, and for the next twenty-five years figured prominently as a peacemaker in the controversies of that period. He took great pains to ascertain and transmit the apostolic tradition as to Christian doctrine and practice, and did good service in establishing the unity of the Old and New Testaments. He was the first writer to treat the Bible as an inspired whole, and took a prominent part in the formation of the New Testament Canon. His chief significance as a theologian consists in his doctrine concerning the Person and Work of Christ. He was the first doctor of the Church who worked out with any thoroughness the great doctrines of the incarnation and redemption, and his treatment of these subjects was by far the deepest and soundest which they received in the ante-Nicene age. His method was to oppose a true Christian gnosis to the heretical gnosis which disturbed the early church. It was by this conflict with Gnosticism (*qv*) that Christian theology was developed and vitalized, and Irenæus was its earliest champion. His acute and striking polemic subverted the interests of philosophy as well as those of religion. He was a writer of painstaking accuracy, and his writings are of the highest value as sources of ecclesiastical history. None of them have survived in the original Greek, but there are very ancient Latin versions of two of them. His *Refutation of Knowledge Falsely so Called*, commonly known as *Adversus Hæreses*, in five books, is our chief source of information as to gnosticism (*qr*) and other heresies. It is one of the most precious remains of early Christian literature and is an inexhaustible storehouse of apologetic materials. His *Proof of Apostolic Teaching*, a later work, is of a more positive character and was written, not to confute heretics, but to confirm the faithful by a defense and exposition of the Christian Faith. W R

**IRNERIUS** (c 1050-1130). — Italian jurist, probably born at Bologna. He was a master of liberal arts and taught rhetoric at Bologna while still comparatively young. Extravagant claims have been made for him as the founder of the study of law at Bologna, and the introducer of glosses. That he was neither has been shown by Rashdall, but his importance in the development of legal study cannot be denied. Previous to the time of Irnerius, the chief center for the study of law was Ravenna. Several circumstances combined to bring about

the decline of Ravenna and put Bologna in the position of importance. Irnerius undoubtedly contributed to this by introducing and lecturing on the new parts of the Digest, hitherto unknown in Bologna, as well as the old, and he was possibly the first glossator of it, the old philosophic study of legal principles was replaced by a closer and more professional study of texts; at this time the whole *Corpus Juris Civilis* began to form the curriculum for students of civil law, the specialization now demanded led to a law faculty as distinguished from liberal arts, and law became a professional study with more mature students. These facts tended to give the law students and law doctors a position of great influence not only in Bologna, but throughout Italy, and to this influence Rashdall traces the rise of the student-university characteristics of Bologna.

Irnerius was the author of a legal formulary (*formularium tabellionum*, see **DICTAMEN**), and of many other works, the chief being the *Summa Codicis*, the earliest medieval system of jurisprudence. He held an important position as an imperial jurist, and his name appears frequently in royal documents from 1113 to 1125. On the question of papal election he supported the claims of the Emperor Henry V.

**IRRADIATION.**—Whenever a portion of the retina is stimulated by a beam of light, there is a tendency for the stimulation to spread over neighboring portions of the retina. The result is a sensation which is not limited to the direct source of the stimulation. Illusions sometimes arise from the spreading of the stimulation. Like phenomena of spreading of irritation have been observed in other parts of the nervous system.

**IRRATIONAL NUMBERS.**—A number that cannot be expressed as the ratio of two integers is called an irrational number. It is not necessary that such a number should be expressible as a terminating decimal. For example,  $\frac{1}{3} = 0.777 \dots$ , and  $\sqrt{2} = 1.4142 \dots$ , but the former is rational while the latter is irrational. There are irrational numbers that cannot be expressed in such a surd form as  $\sqrt{2}$ , as, for example,  $\pi$  and  $e$ . (See **TRANSCENDENTAL NUMBERS**) The modern theory of irrational numbers is due largely to Weierstrass, Dedekind, and G. Cantor. For

this theory the reader may consult Dedekind's *Essays on Number* (translated by Beman), Chicago, 1901. The theory is not simple enough for the secondary school, so that there the work must be confined to the recognition of the common laws of operation with these numbers. The tendency at present is to eliminate from the secondary school all work with irrationals of a complicated nature, reserving this until the theory can be studied more fully in college. In particular, the extracting of the square root of a binomial surd, a subject of practical value before the invention of the decimal fraction, is now commonly omitted in this type of school, at least beyond the most elementary case.

See also **ROOTS**; **INCOMMENSURABLE QUANTITIES**.

**IRRITABILITY.**—The disposition of organic substance to undergo certain marked physiological changes under the influence of incident forces which act as stimuli. All living substance is irritable in that it is capable of reacting, in some way, to stimuli. The term is primarily a physiological one, and it has no psychological implications. In other words, irritability may, for all that is known, exist in the absence of sensibility. Nerve and muscle cells are commonly said to be highly irritable because upon the application of certain forms of energy they undergo pronounced changes. The nerve cell, when acted upon, may give rise to a nervous impulse, the muscle cell may entirely change its form. These two kinds of cells are first thought of as possessing irritability, because their expressions of this property are more striking than those of most types of cell.

**ISELIN, ISAAK** (1728–1782) — Swiss author and philanthropist. Born at Basel, he studied law at Gottingen, and after traveling for some years obtained an appointment at Basel as Secretary to the Council. He devoted himself almost immediately to public and political questions. His chief philosophical works were *Geschichte der Menschheit* (*History of Mankind*, 1764), and *Traume eines Menschenfreundes* (*Dreams of a Philanthropist*, 1776), in which from a viewpoint opposed to that of Rousseau the progress of man is the upward progress of reason to happiness and perfection. Iselin's main interests, however, seem, as with so many other Swiss leaders at this period, to have lain in education for the improvement of the nation and humanity. In 1760 he played an important part in organizing the *Helvetische Gesellschaft*, and in 1777 the *Gesellschaft der Guten und Gemeinnutzigen* (Society for the Public Welfare), which has continued to the present

In 1760 he was appointed on a commission to consider measures for the improvement of the Basel gymnasium. He had already offered suggestions in 1757 for the improvement of the university in *Unvorgreiflichen Gedanken über die Verbesserung des Baselschen hohen Schulen* (*Humble Thoughts on the Improvement of the Basel High Schools*.) In 1768 he wrote a collection of stories for children (*Sammlung den Nutzen und Vergnügen der Jugend gewidmet*). In the same year appeared *Über Erziehung* (*On Education*), in which there is a demand for an education to train men to the highest, noblest, and best, not through abstract ideas, but by pleasurable, interesting, and concrete methods. Such work was for the philosopher who thoroughly understands children. At this time Basedow's *Vorstellungen* came into his hands, and thenceforth Basedow had no warmer friend and supporter. Iselin secured subscriptions, brought the *Appeal* to the notice of the *Helvetische Gesellschaft*, and hoped that such a school would be established in Switzerland. In *Über die Erziehungsanstalten* (*On Educational Institutions*) the author makes a proposal for institutions in which different classes of society could be educated for life's work side by side for their mutual welfare. The education of girls is also insisted upon. Above all, Iselin seems to have welcomed the possibility of training teachers opened up by Basedow, and he assisted four Swiss students to proceed to Dessau for training. He continually kept the merits of the Philanthropinum and the movement connected with it before the public in *Ephemeriden der Menschheit oder Bibliothek der Sittenlehre und der Politik* (1776-1782).

How great was Iselin's service to Pestalozzi, it is impossible to estimate. After meeting with repeated failure in his attempt to secure the publication of *Leonard and Gertrude*, Pestalozzi turned to Iselin, who read through and corrected the *Ms.*, secured a publisher in Berlin, and arranged for a reasonable remuneration for the work.

The *Gesellschaft der Guten und Gemeinnutzigen*, of which Iselin was the moving spirit, devoted a great part of its labors to education; it offered prizes for attendance and drawing; distributed readers, taught special subjects such as singing, geometry, and needlework; encouraged gymnastics and opened a girls' school in 1812, founded libraries for children and adults, museums, a civic newspaper; conducted children's festivals; and apprenticed boys on leaving school.

**ISIDORE OF SEVILLE, or ISIDORUS HISPALENSIS**—A Spanish bishop who flour-

ished in the late sixth and early seventh century. He was noted for his learning, eloquence, and ability, and was the author of numerous treatises. His importance educationally, however, depends upon his one work, the *Etymologiarum Libri XX* or *Origines*. This was an encyclopedic work covering all branches of knowledge which served throughout the Middle Ages as a textbook of higher learning and a source of general information. For his sources the author depended quite generally upon second-hand information, and was not very particular as to its character. Yet it was convenient and an authoritative church summary and as such exerted wide influence. The titles to the various books are as follows: (1) Grammar; (2) Rhetoric and Dialectic, (3) Arithmetic, Geometry, Music, and Astronomy; (4) Medicine, (5) Law and Chronology (history); (6) Ecclesiastical books and offices; (7) God, angels, and the orders of the faithful, (8) Church and the sect, (9) language; (10) Society and relationship; (11) Man and habits; (12) Animals; (13) The world and its parts; (14) The earth and its parts; (15) Buildings, fields, and their measures; (16) Stones and metals; (17) Agriculture, (18) War and games; (19) Ships, buildings, and garments; (20) Provisions, domestic and rustic instruments. F. W.

**ISOCRATES** (436-338 B.C.).—The Athenian orator and rhetorician played an important part in the educational history of the fourth century. Educated under the leading sophists, Prodicus, Protagoras, and Gorgias, he became a professional logographer or advocate, i.e. he wrote speeches for clients engaged in lawsuits. About 390 B.C. he opened a rhetoric school at his home near the Lukeion. In his speech, *Against the Sophists*, written c. 390 B.C., he attacks those who attract pupils by low fees and big promises of imparting absolute and universal knowledge and eloquence without regard to the natural ability of the pupil. He aimed to prepare for an active public life, and this preparation consisted in a study of philosophy or a training in the formation of correct judgments by practice in deliberation and debating. He took pupils from the ages of about fifteen to twenty-one and charged ten minæ (about \$200) for the course of three or four years. Students from all parts of the

Greek-speaking world flocked to him. He expected a previous knowledge of mathematics and sciences, and his own course consisted of essay writing and speeches on all manner of topics, practical, political, theological. Emphasis was laid on style, diction, and matter. Speeches written by himself or others, including those of pupils, were studied, and subjected to criticism and revision. By a wise selection of themes and by inculcating high standards, Isocrates claimed that his course in itself was an excellent training of character, for he did not hold that virtue was teachable. The success of his school was evidenced not only by his own great wealth, but by the number of his students who attained eminence in all walks of life, as rulers, statesmen, orators, lawyers, and historians. The truly educated man is distinguished by good taste, sound judgment, correct behavior, self-control, and modesty. Culture and polish were the ends of education, for, as he says, "Those whose soul is well trained to play its part in all these ways, those I call wise and perfect men, and declare to possess all the virtues; those I regard as truly educated." This ideal in almost identical terms is, of course, also characteristic of the Renaissance. Towards the close of his career (354 B.C.) his great wealth drew on him an attack from one of his many rivals whom he had so often criticized. In his defense, *Antidosis*, or *On the Exchange of Estates*, he sums up his career as a teacher and defends himself and rhetorical training. For the use of selected *Orations* of Isocrates in modern schools, see GREEK, STUDY OF.

**ISOLATION** — A term used to express the opposite of correlation (*q.v.*), in instruction, or the method of teaching subjects as separated from one another. It is claimed that only by recognizing arithmetic, geography, history, etc., as independent studies, adequate and complete in themselves, can each subject attain its own due rights and realize its own appropriate end. The logical idea underlying this contention is that the various subjects represent something beside convenient distinctions carved out within a comprehensive unity; it assumes that there are just so many objectively important phases of reality, and that each subject (or group of subjects) stands for just one of these phases. Accordingly by isolation of each subject and then by coordination of the various independent subjects, the subject matter of instruction will be rendered both definite and harmoniously complete.

It may be replied that, philosophically speaking, both isolation and correlation represent stages in growth from the more direct and vital forms of experience to its logical formulation, that is, its organization for purposes of better intellectual control. Experience does not begin with a number of sharply marked off fields, or topics, either requiring to be made more distinct and definite in their separations, or else needing to be bound up together by various correlating devices. It begins with a vague, somewhat confused and fluctuating unity, whose parts flow readily into one another, these parts being marked off by various interests and purposes, rather than by objective or logical differences. Growth takes place by a movement toward differentiation, on one hand, and toward interrelation of discriminated parts on the other. Isolation thus represents a goal toward which instruction and learning are moving, not original divisions. The distinctive character of mathematics, as a subject on its own account having its own unique material and special method, follows after a term of study marking the attainment of a logical comprehension. Even then it is undesirable that differentiation should be carried to the point of isolation in its literal sense. For the purposes of all education save that of the specialist it is needful that the interdependence of each study with the other studies — their mutual applications to one another and to life — should be borne in mind. This requirement is met only when correlation and differentiation are used to supplement each other, instead of being treated as rivals. J. D.

**ITALY, EDUCATION IN** — Italy is a parliamentary monarchy. Its area is 286,682 square kilometers, its population 34,688,653 (1911). The territory is divided into 69 *province* and over 8000 *comuni* (towns and villages). The affairs of a province are administered by a *Consiglio provinciale* (provincial council), elected by the people, and a *Deputazione provinciale* elected by the *Consiglio* from among its members. The affairs of a *comune* are likewise administered by a *Consiglio comunale*, elected by the people, a *Sindaco* (mayor), and a *Giunta comunale* (communal committee), elected by the *Consiglio* from among its members. A government officer, the *Prefetto*, supervises all local bodies. Provinces are for administrative purposes subdivided into *circondari* (circuits) or *distretti* (districts). The town in which the *Prefetto* resides and the *Consiglio provinciale* meets is called *Capoluogo di provincia*, and gives the name, as a rule, to the province. Likewise, the administrative

center of a *circondario*, or *distretto*, is called *Capoluogo* (chief town) *di circondario*, or *distretto*.

**HISTORICAL DEVELOPMENT.**—Italian education, as a part of Italian culture, is a direct outgrowth of Roman society and has its origin even in pre-Roman times. The consideration of these historical foundations of modern conditions is given under Roman Education. The Roman schools continued until well into the Middle Ages, and the discussions of education during the Middle Ages (*q v.*) applies particularly to Italy. So, too, the discussion of Monasticism and Education and the minor topics such as Abbey Schools, Bishops' Schools, etc., relate particularly to Italy. Universities took their rise in Italy, and the discussion of origins under this topic has special reference to Italy. Again, with the period of the Renaissance, the educational and cultural influences had their origin in Italy, and the survey of education during the Renaissance (*q v.*) forms but a chapter in the history of Italian education. The Teaching Orders (see JESUITS, etc.) furnished many schools after the Reformation. After the Council of Trent (1545) seminaries were established in many places, and, though primarily intended for the training of the clergy, laymen were also often instructed in them. The academies and private schools of both secondary and elementary type furnished a well-developed system of schools for Italy during the early centuries of the modern period. These were established by princes, by teachers, by cities, or by private endowment, or by ecclesiastical authority of various types. Some of these schools were very noted. In some instances there was an approach to a local system of schools. Venice, for instance, had public schools very early, and in 1551 it was ordered that each section of the city should maintain a grammar school. However numerous, these schools cannot be regarded as constituting a system of education, though provisions were made by some of the states to regulate the whole matter. One of the earliest is perhaps that of Victor Amedeus II, of Sardinia (1729). Education in the first half of the eighteenth century fell to a very low plane; in the second half there is the beginning of a revival. In Lombardy, then under the Austrian crown, were introduced the reforms of Maria Theresa and her successors. (See AUSTRIA.) After the invasion of the French at the end of the eighteenth century and at the beginning of the nineteenth, Italy passed under the rule of France, either directly, as Piedmont, Genoa, Rome; or indirectly, as the kingdoms of Naples and Italy, and laws were enacted following the French model. The fall of Napoleon brought back the old régime, and very little, if anything, was done to promote public education, though universities and many schools were state or municipal institutions more or less controlled by the clergy. The kingdom of Sardinia had a general statute pertaining to education

(1824); Lombardy and Venetia, under Austria, followed Austrian laws; other states had no general statutes.

**THE PRESENT SYSTEM OF EDUCATION.**—The fundamental law that regulates public instruction in Italy is the Casati act of Nov. 13, 1859. When promulgated, it applied only to the kingdom of Sardinia; that is, Sardinia, Piedmont, Liguria, and Savoy, and Lombardy; it has since been extended, with some changes, to other parts of the kingdom of Italy. The lack of another general act, however, has caused many parts of it to be applied more or less legally to the whole kingdom, and it has been the basis of most of the acts dealing with particular phases of education.

**Central Administration.**—At the head of the national system is the Minister of Public Instruction. He is a member of the cabinet and either a deputy or a senator. His control extends to all orders of public instruction, military and naval schools excepted, and to all officers charged with the inspection of public schools and higher institutions. The Minister decides upon all disputed questions, revises the decisions of his subordinates, and, by means of his officers or other persons designated by him for the purpose, supervises private schools and institutions of instruction and education. In the case of refusal to conform to the laws, he may order the schools to be closed, after consulting the Higher Council. Next in importance to the Minister is the Undersecretary of State for Public instruction, who takes charge of the affairs intrusted to him by the Minister, substitutes for him during his absence, and may represent him in the Chamber of Deputies and the Senate.

The highest body dealing with public instruction is the Higher Council (*Consiglio Superiore*). According to Act 496, of 1909, this Council consists of thirty-six members, chosen as follows: six senators elected by the Senate, six deputies elected by the Chamber (senators and deputies so elected must not be university professors), twelve members nominated by the Minister, and twelve designated by ordinary and extraordinary university professors. Members are selected or appointed for four years and cannot be reelected within two years from the close of their terms of service; half of the Council is renewed every two years. Before the passing of this act, there were only thirty-two members, none of whom were elected by Senate or Chamber. The change was bitterly opposed by many professors, who feared that senators and deputies would bring politics into the Council. The Minister is the chairman of the Council. A Vice-President is appointed by the King for two years. The Council meets regularly twice a year, in spring and fall, but the Minister may call an extra session at any time. The Council in committee of the whole at the request of the Minister prepares and examines all bills, by-

laws, and general provisions relating to the organization of schools, appointment of professors, etc. The Minister cannot dismiss or suspend a professor unless the Council concurs.

Within the Council there is a committee (*Giunta*) of fifteen members appointed by the Minister from the councilors. To this committee, which meets once a month and may be called together by the Minister or Vice-President at any time, all affairs pertaining to higher education not coming before the full council are referred. Affairs of special moment are first considered by a section of at least five members of the committee who submit their report to the full committee for a final discussion. A special section of the committee, created by an act of 1906, deals with matters pertaining to secondary education. This section is composed of four councilors, members of the committee (one being chairman of the committee of the section), appointed by the Minister; one director and two teachers of government secondary schools, who must have taught seven years, and one director or teacher of schools, recognized as equivalent to government schools, elected by the directors and teachers of those schools. Another special section of the committee, created by the act of June 4, 1911, deals with matters pertaining to primary education. This is composed of three members of the Higher Council appointed by the Minister, the director general of elementary education, a head master and a teacher of normal schools elected by all head masters and teachers, an inspector selected by the Minister, a director of primary education and two elementary teachers selected by all directors and teachers, and another member with a knowledge of education appointed by the Minister.

The Ministry of Public Instruction is also assisted by permanent committees which advise on particular subjects. Among these are a central committee for diffusion of education in southern Italy and Sardinia and Sicily (*Commissione centrale per la diffusione dell'istruzione elementare nel mezzogiorno e nelle isole*) and a committee to pass on all controversies relating to primary education (*Commissione consultiva per le controversie relative all'istruzione primaria*).

The Ministry of Public Instruction is divided into four bureaus (*Direzioni generali*),—elementary and normal education, secondary education, higher education, and fine arts respectively; and two independent divisions (*Divisioni*) with a total of 191 employees of higher grade, including 26 inspectors, 62 accountants, 128 minor clerks. All employees are subject to the general act 290 of June 25, 1908. They are appointed by competitive examination, and vacancies are filled by promotion, those of higher grades by examination. The chiefs of bureaus are chosen by the council of Ministers; they may also be persons not belonging to the administration.

The salary of the Minister is 25,000 lire, of the undersecretary 12,000, of chiefs of bureaus (*Direttori generali*) 10,000 lire. That of higher grade clerks and accountants varies from 2000 to 8000 lire, that of minor clerks from 1500 to 4000 lire (1 lire = 18 cents.)

*Local administration*—In each province there are: (a) A *Provveditore* who has charge of everything relating to public instruction in the province. The sixty-nine *Provveditori* have salaries varying from 5000 to 8000 lire. (b) A *Consiglio provinciale scolastico* (Provincial education council) of fifteen members including the *Provveditore*, who is the chairman, representatives of the *Consiglio provinciale*, of the *Consigli comunali*, of teachers, etc. The *Consiglio* has the general supervision of elementary schools and the direct administrations of schools for most of the *comuni* (see below). (c) A *Deputazione scolastica* (Education committee) of seven members including the *Provveditore*, who is the chairman. It prepares the budget and all affairs to be submitted to the *Consiglio*. (d) A *Delegazione governativa* (Governmental committee) which revises the accounts of the *Consiglio*. (e) A *Giunta provinciale per le scuole medie* (Provincial council for middle schools) which has the general supervision of secondary schools of the province.<sup>1</sup>

*Istituti tecnici and nautici*, and schools under the Ministry of Agriculture, Industry and Commerce are not under the *Giunta*, but each of them has a special supervisory committee, that of the former called *Giunta di vigilanza*. Universities and schools of university rank are independent of local authorities.

**Primary Schools.**—Under the Casati act all *comuni* had the direct administration of their schools, the state contributing to the expenses and having the general supervision. In this respect the act of June 4, 1911, has made radical changes. *Comuni capoluogo di provincia* and of a *circondario* or *distretto*, the last, if they have a population of more than 10,000, will retain the administration of their schools. The *capoluoghi di circondario* or *distretto* may within three years from the promulgation of the act waive the right to administer their schools. *Comuni* which by the census of 1911 have less than 25 per cent of illiterates, provided they have fulfilled all requirements of the laws relating to elementary education for the last five years, may retain the administration of their schools, but are not obliged to do so. Schools of other *comuni* will be administered by the *Consiglio provinciale scolastico*.

The Casati act provided for a full system of elementary education, though not compulsory. According to it elementary schools were divided into two grades, each completed in a term of two years, the child entering the first class at

<sup>1</sup> The *Deputazione*, *Delegazione*, and *Giunta* were created by the act of June 4, 1911. Formerly the *Consiglio provinciale*, differently composed, had supervision of primary and secondary education.

the age of six or seven. The course of study of the lower grade covered religious instruction, reading, writing, elements of arithmetic, Italian language, and elements of the metric system. That of the higher grade included, besides the subjects of the lower grade: composition, penmanship, accounting, elements of geography, the most important events of national history, the elements of physical and natural sciences, chiefly in their application to everyday life; also in the higher grade schools for boys the elements of geometry and geometrical drawing; in those for girls, needlework.

Compulsory education was established by the act of July 15, 1877, known as the Coppino act, which required all children to attend school from six to nine, or ten, if they did not pass the prescribed examination. By this act the subjects of instruction for the three compulsory years were elements of civics, reading, penmanship, the rudiments of the Italian language, arithmetic and the metric system. The omission of religious instruction excited much opposition, but without effect. The obligation placed by the earlier act upon *comuni*, having a population of over 4000 or possessing a secondary school, to maintain elementary schools of the higher grade, was not changed by the Coppino act.

At the time of the passage of the act of 1904 (Orlando act) there were: (a) *comuni* which had established the whole course of five classes either because obliged to do so, or voluntarily, (b) *comuni* which had established schools with four classes though not obliged to establish the fourth, (c) all other *comuni* having only the three classes of the lower grade. The act of 1904 changed nothing as to the *comuni* of division (c), but it required those of division (a) to establish within three years a sixth class, reducing the teaching hours to three daily in the fifth and sixth classes, and assigning both of them to one teacher. In these *comuni* the age limit was extended to the twelfth year unless the Minister recognized that the expense involved was too great. The act forbade *comuni* of division (b) to close any of the schools voluntarily opened; here compulsory education has been extended to all existing school classes. *Comuni* of divisions (a) and (b), which had voluntarily opened classes of the higher grade and charged a fee, have been authorized to maintain the fee, though attendance has been made compulsory.

The syllabus for the fifth and sixth classes covers: Italian language, Italian history of the nineteenth century, civics, geography, arithmetic, geometry, accounting, domestic economy, natural sciences and hygiene, penmanship and drawing, and, in schools for girls, needlework. Singing, manual training, agriculture, and other subjects may be added by the *comuni*. Pupils intending to enter secondary schools leave the elementary schools at the end of the fourth year, when they take a special examina-

tion called *maturità* examination at ten years of age, for which a fee of fifteen lire is charged; pupils who have followed the whole course of six classes may be admitted, under certain conditions, to the second class (year) of the *Scuola tecnica*.

The act of 1904 made more stringent provisions for enforcing compulsory school attendance and provided for the establishment of 3000 evening and Sunday schools for illiterate adults in those districts where the number of illiterates is highest. Special provisions for the diffusion of elementary education in the southern and central provinces were made by a later act of 1906.

The act of June 4, 1911, has gone much farther toward improving the conditions of elementary education; under its provisions the state assumes a larger part of the expenses. In each *comune* a *patronato scolastico* is established in order to further encourage attendance and efficiency by the distribution of free meals, clothes, establishments of libraries, etc.

*Teachers* — Teachers in *comuni*, which retain the administration of their schools, are appointed by the *Consiglio comunale* with the approval of the *Consiglio provinciale scolastico*. Those of other *comuni* are appointed by the *Consiglio provinciale scolastico*. Salaries in force from Jan. 1, 1912, have been fixed by the act of June 4, 1911, and range from 1200 to 1700 lire for teachers in graded schools, *i.e.* in larger *comuni*, for boys or boys and girls, and from 1050 to 1500 for teachers in graded schools for girls. For schools not graded, namely, in very small villages, salaries are 500 and 800 lire. Teachers in charge of two classes have an extra compensation of 300 lire. All teachers have four increases, equal to one tenth of their salary, once every six years. Some of the *comuni* pay considerably higher salaries. Rome pays from 1800 to 3100 lire, Milan from 1850 to 2900 for men and 2600 for women, Venice from 1700 to 2200 for men and 1400 to 1800 for women. Legally no one can be appointed as a teacher unless he has secured a diploma; but the appointment can and often does go temporarily to any one who, in the estimation of the *Provveditore*, is able to take charge of the class. The teacher is first appointed for a term of three years, if reappointed, he can be dismissed only for cause. No man can be appointed teacher under eighteen years of age, and no woman under seventeen years of age. All teachers receive a pension upon retirement, either from a special pension fund established for that purpose or from the *comuni*, if the *comuni* had provided a system of pensions before the pension fund was created. *Comuni* contribute to this fund five per cent of the salaries paid to their teachers. The teachers pay four per cent. The state also contributes.

To supervise elementary schools there are *direttori didattici* (school directors in the *comuni*,

## ITALY

who have the administration of their schools; sub-inspectors (1000 in the whole country newly established by the act of June 4, 1911, at salaries from 2000 to 2400 lire, part of them replacing *direttori didattici* of smaller *comuni*), and over them inspectors (400 in number at salaries from 2500 to 4500). There are also ten central inspectors connected with the Ministry with salaries of 6000 and 7000 lire

*Cost of Education* — The expenses for elementary schools are borne by the *comuni* with contributions from the State. In 1899 the State paid nearly 4,000,000 lire, the provinces less than 400,000, and the *comuni* 64,000,000, making a total of 68,400,000 lire. This is less than three lire per capita while at the same time the expenses of Great Britain and the United States were nearly twelve lire and those of Germany over nine per capita. Under the Education Acts of 1886 and 1900, and more especially those of 1904 and 1906, the State has increased its share of the expenditure. It amounted to nearly fourteen million lire for the fiscal year 1906–1907, to nearly eighteen for 1907–1908, to twenty in 1908–1909, and to nearly twenty-four million in 1909–1910. The act of 1906, applying to southern and central Italy, Sicily, and Sardinia, provided for more than 18,000 new schools at an expenditure of more than 18,000,000 lire, of which above 11,000,000 will be contributed by the state and 7,000,000 by the *comuni*. Five years were allowed for carrying out the provisions of this act. The act of June 4, 1911, has further provided that within three years all rural schools shall be reorganized. The higher expenses caused by the increase of salary of teachers, and the establishment of new schools will fall upon the State. The Bank of Deposit and Loans will lend to the *comuni* 20,000,000 lire a year for twelve years and the State will pay the interest on this sum. It is estimated that the total expense of the State will rise from nearly 34,000,000 lire for the fiscal year 1910–1911 to nearly 74,000,000 lire for the fiscal year 1920–1921. The share of the expenses for the *comuni* whose schools will be administered by the *Consiglio* will be fixed at the highest figure of their expenses for schools for the years 1909 or 1910 and turned over to the *Consiglio*.

**Statistics** — Recent statistics cover only government schools and those recognized as equivalent to them. General statistics are not issued oftener than five-year periods. The last statistics covering all kinds of schools relate to the school year 1901–1902 for normal and *complementari* schools and special schools for girls; those for all other schools are much older. The most recent general statistics available are for 1907–1908.

Additional schools needed above number for 1907–1908, 27,000. State of schoolrooms (1907–1908): good, 21,028; poor, 20,233; unsatisfactory, 18,806; total, 60,067.

## ITALY

### STATISTICS OF PUBLIC ELEMENTARY SCHOOLS

SCHOOL YEAR	SCHOOLS (i.e. grades)	TEACHERS	PUPILS
1871–1872	33,556	34,309	1,545,790
1877–1878	39,702	39,702	1,830,749
1882–1883	42,390	43,659	1,873,723
1887–1888	42,247	47,998	2,125,207
1892–1893	49,722	51,385	2,291,966
1901–1902	53,259	56,433	2,548,583
1907–1908	63,618	60,323	3,002,168

*Pupils.* — The total number of children from six to twelve years of age was 4,500,000 (estimated); obliged to attend school 3,949,141 (1907–1908); enrolled in public schools, 3,002,168, or 93 per cent of population.

### SCHOOL YEAR 1907–1908

GRADES	PUPILS ENROLLED	PUPILS WHO PASSED THE FINAL EXAMINATION
1st	1,260,317	633,378
2d	856,587	479,792
3d	607,317	310,846
4th	181,323	106,656
5th	77,875	52,751
6th	18,749	13,052
Total	3,002,168	1,596,475 or 58.90 per cent of pupils enrolled

### EXPENDITURE (LIRE)

Fiscal Year	State	COMUNI		Per cent of total expen- diture	Per cap- ita
		Calen- dar year	Total		
1903–1904	5,756,171	1899	66,350,966	14.18	2.07
1910–1911	26,791,116	1909	136,023,760	15.52	4.00

### EVENING AND SUNDAY SCHOOLS FOR ADULTS

Established under Acts of 1904 and 1906, 4783 (1907–1908)

ENROLLED		WHO TOOK THE EXAMINATION	WHO PASSED IT
Men	148,233	78,314	61,543
Women	34,140	19,689	16,174
Total	182,373	98,003	77,717

Private Schools (1907–1908) · schools, 3504; Grades, 11,904, schoolrooms, 6534; pupils, 148,081; principals, 2063; teachers, men, 1318; women, 4749; total, 6067

The number of private schools is about the same as reported for 1901-1903, the number of teachers has decreased. Kindergartens for 1907-1908<sup>1</sup> numbered 4967, teachers were 7393; pupils were 378,563

**Secondary Education — General Regulations.** — The secondary schools are regulated by the Casati act, but the full provisions of that measure, as regards the number, location, and support of the several classes of secondary schools, have never been realized. As a rule the buildings and equipments for the secondary schools are provided by the local authorities and the current expenditures by the state and local authorities, the proportion borne by the latter having been fixed by an act of 1904 and amending act of 1907, for the schools taken over by the state hereafter.

In the normal and *complementari* schools the salaries of teachers, the expenses for scientific and teaching material for the laboratories and for the library are paid by the state, the salaries of teachers in the elementary schools, the cost of the building, its care and janitors' salaries are paid by the *comuni*. Any one having the moral qualification may open a secondary school provided he gives notice to the *Provveditore* or the chief of the *Giunta* (Committee) of the *Istituto tecnico* of the province, if he wishes to open such a school, or to the Minister, if there is no *Istituto tecnico* in the province. Teachers must have diplomas. The students of private secondary schools must pass the government examinations to secure the recognition of their studies. *Comuni* provinces and other public corporations may establish secondary schools; such schools may under certain conditions be recognized as equivalent to government schools.

**Types of schools.** — The secondary schools are classified as follows —

(I) Classical schools and modern schools with Latin (a) *Ginnasio*—five years' course, (b) *Liceo*—three years

(II) Modern schools without Latin, and technical schools: (a) *Scuola tecnica* and *Scuola complementare*—three years, (b) *Istituto tecnico*—four years, and *Istituto nautico*—three years.

(III) Normal schools. (a) as II; (b) *Scuola normale*—three years, or (a) as I, (b) *Corso magistrale*—two years

*Ginnasio*, *scuola tecnica*, and *scuola complementare* are schools of the first grade, *Liceo*, *istituto tecnico*, *istituto nautico*, and *scuola normale*, of the second grade. In cities having *ginnasio* and *liceo* the two institutes are combined in one *liceo-ginnasio*. Candidates for admission to a secondary school must pass the *maturità* examination

The full classical course, it will be seen from

the above outline, covers eight years; the full modern course, seven years. Girls are admitted to all secondary schools on the same terms as boys, but the *scuola complementare* is exclusively for girls. The plan of studies for the *ginnasi* includes Italian, Latin, Greek, French, history, geography, mathematics, natural history; that of *licei*, philosophy, physics and chemistry and the subjects taught in the *ginnasi* with the exception of French. The plan of studies of the "modern" *ginnasi* established by act No 860 of July 21, 1911, includes Italian, Latin, French, German or English, geography and history, mathematics, natural history, drawing, and physical culture, that of the *licei* includes in addition political economy, philosophy, elements of civics, physics, chemistry, astronomy, and physical geography. These new schools will be established in those cities having more than one *liceo-ginnasio*, and only the fourth class of the *ginnasio* will be established for the school year 1911-1912, the fourth and fifth in 1912-1913 and so on. The studies of the *scuola tecnica* are Italian, history, the elements of civics, geography, French, mathematics, the elements of natural sciences, drawing, penmanship. A few schools have special courses comprising besides the above with slight changes, (a) agriculture, (b) accounts and English or German, (c) the elements of mechanics and technology. These new plans have been established recently (1899) and in a few schools only. The studies of the *scuola complementare* include Italian, geography, Italian history, the elements of mathematics and accounting, the elements of natural and physical science and hygiene, French, drawing, needlework, gymnastics. There are also numerous special schools for girls, mostly boarding schools, with plan of studies similar to those of *scuole complementari*.

Technical schools (*istituti tecnici*) are divided into sections (*sezioni*). The three most important are: (a) physico-mathematical section (*sezione fisico-matematica*), (b) surveying, building and agricultural section (*sezione di agrimensura*), (c) accounting and commerce section (*sezione di commercio e ragioneria*). A few *istituti* have also (d) agricultural section (*sezione di agronomia*), (e) industrial section (*sezione industriale*). The plan of studies for all sections includes Italian, history, geography, French, drawing, logic and ethics, natural history, physics and chemistry, and mathematics; the various subjects, however, do not cover the same ground for all sections. Additional subjects are, for section (a) higher branches of mathematics, and German or English; (b) agriculture, building and drawing, real estate and building law, surveying and drawing and descriptive geometry, (c) accounting; commercial, administrative, and civil law; political economy; finance and statistics, English or German. Sections (d) and (e) have special programs.

<sup>1</sup> Kindergartens are regarded as charitable institutions, and therefore are under the supervision of the Minister of the Interior, the State grants them subsidies from a special appropriation for that purpose

The Nautical Institutes are divided into three sections (a) engineering section, (b) nautical section, (c) shipbuilding section (for small crafts only). The plan of studies for all sections includes, though in different measure, Italian, history, mathematics, physics, mechanics, English. Also for section (a) applied mechanics, steam engines, drawing, materials of construction and fuels, engineers' duties, and ship practice; for section (b) navigation, seamanship, astronomical geography and nautical astronomy, steam engines, meteorology, commercial geography, maritime law and accounting, for section (c) applied mechanics, steam engines, naval construction and drawing, material of construction, theory of the ship, law.

Connected with the technical and nautical schools there are evening courses, and with the nautical schools also preparatory schools, and special courses at one of them (*Piano di Sorrento*) for foremen in shipyards.

The plan of studies for the normal school for boys includes pedagogy, ethics, Italian, history, geography, the elements of mathematics, accounting, physics, chemistry, natural history, and hygiene, drawing, penmanship, singing, agriculture, gymnastics, practice in elementary schools, and manual training. The normal schools for girls include all above subjects, except manual training and needlework, domestic economy, and practice in the kindergarten. Owing to the scarcity of men teachers special two years normal courses (*corsi magistrali*) have been established in towns having *ginnasi* only, by act of July 21, 1911. Boys and girls will be admitted if they have passed the *licenza* examination of the *ginnasio*. Not more than fifteen of such courses may be opened during 1911-1912, 1912-1913.

**Examinations** — Under the examination by-laws of 1904 all pupils as a rule undergo three examinations, written and oral or only oral, during the school year, in December, March, and June. Marks are given to each pupil by the teacher of each subject on general efficiency during the three months preceding each examination, and on all examination papers by the teacher of the subject and another teacher. The highest mark is ten and the pupil who averages six in the above examinations and seven for good behavior in all subjects is admitted to the next class (*i. e.* year of study); if he does not average six, he must present himself for examination in October. If he fails to pass, he must repeat the year of study and he must also do so, if he gets less than five marks for good behavior in more than one half of the number of subjects.

At the end of each school course the pupil must pass a special examination called *licenza* examination, unless he has obtained eight marks in the examinations during the last year. The *licenza* from the *ginnasio* is required to enter the *liceo*, that of the *scuola complementare* or

*scuola tecnica* to enter the *istituto tecnico* or *nautico* or the *scuola normale*. Admission to the *Istituto tecnico* is obtained also through special examination. A *licenza* certificate from a government or equivalent school is necessary to take the civil service examinations or to enter the universities or higher schools.

Pupils studying at private schools may take an examination to enter any class of the schools, except normal schools, or the *licenza*. If they wish to enter the second class of a school of the first grade, they must have passed the *maturità* examination at least one year before, if the third class, at least two years before, etc. If they wish to enter the second class of a school of the second grade, they must have passed the *licenza* examination of the corresponding school of the first grade one year before; if the third class, two years before, etc. Admission to the second or third year of the normal school cannot be obtained by any but regular pupils of a government school.

**Fees** — The fees to be paid by pupils of government, or equivalent schools, for the whole course including examination fees (part of which is reserved to the teachers), vary from 106 to 409 lire. Clever pupils, if in needy circumstances, are exempted from payment. Pupils who have studied privately pay higher examination fees.

**Teachers**. — No one can be appointed teacher in any government or equivalent schools or teach in any private school unless he has a degree granted from a university or school of the same standing, or a special diploma, which can be granted only after examination and for such subjects as are not taught in universities. These are modern languages (though there are some courses at a few universities), drawing, accounting, penmanship, and stenography. The status and compensation of teachers in government and equivalent schools are regulated by the two acts of April 8, 1906, nos. 142 and 144, which fixed the rules to be followed in appointing, dismissing, transferring from one place to another, censuring, etc., any teacher. The first appointment is for three years, after which it is made permanent, if the inspectors report favorably, if not, the appointment is extended for another year, when the teacher is definitely appointed or dismissed. During this probationary period the teacher (*professore*) is called extraordinary (*straordinario*), after the definite appointment, ordinary (*ordinario*). Not all places, however, are filled by teachers so appointed. In certain cases, when a teacher would have only a few hours a week, a temporary appointment is made. Such appointments are also made if a regular appointee cannot be found for the place, and in schools with a large number of pupils, when it is necessary to divide classes and the regular teacher cannot take charge of all. As a rule, a teacher is appointed for a single study or for two related subjects.

**Salaries.** -- The scale of salaries paid to teachers in secondary schools varies considerably with the subject taught. Here only the salaries paid to teachers of subjects which are definitely secondary are given. (a) All teachers of secondary schools of the first grade, with the exception of teachers of the fourth and fifth class (year) of the *ginnasi*, and teachers of drawing and penmanship in the normal schools for boys, and of drawing in the normal schools for girls, have salaries of 1800 lire if extraordinary, and from 2000 to 4800 if ordinary. (b) All other teachers of secondary schools of the second grade and those of the fourth and fifth class of the *ginnasi* have salaries of 2200 lire if extraordinary, and from 2500 to 5400 if ordinary.

All ordinary teachers have four increases in salary of 500 lire each, every five years. Then two increases, one tenth of the salary thus reached, each at six years interval. In this way they pass from the minimum to the maximum salaries, as given above. The four fixed increases, but not two consecutive ones, can be anticipated one year in case of exceptionally able teachers.

Teachers, like all the government employees, receive pensions on their retirement from service.

Teachers of class (a) have to teach from fifteen to eighteen hours, of class (b) from thirteen to fifteen hours, of the other classes a number of hours which varies from four to fifteen, according to the subjects. If they teach more, they receive extra pay. Extra pay, varying from sixty to one hundred and fifty lire a year, is also granted to those teachers who have charge of laboratories or have to correct exercises at home, etc. All receive part of the examination fees paid by the pupils.

Headmasters are appointed from teachers who have taught for thirteen years and from a list compiled by the *Giunta del Consiglio Superiore, sezione scuole medie*, in accordance with results of the inspections. They are appointed for a first period of five years during which they teach and receive extra compensation varying from 750 to 1000 lire a year. After the probationary period, they are permanently appointed and receive salaries not higher than 5750 lire for schools of the first grade, and 6500 for schools of the second grade, and they may be relieved from teaching.

Schools equivalent to government schools must pay the same salaries.

**Inspection.** -- A new body of inspectors for secondary schools was formed by Act 414 of June 27, 1909. For the purpose of this act the whole of the kingdom is divided into twenty-one districts. In September each year by order of the Minister, inspectors are assigned to each district; for certain subjects one inspector may be assigned to more than one district. The appointments are for a year and may be renewed for two following years, after which one

year must elapse before the appointment can be renewed.

Inspectors are chosen from among (a) Professors of universities and schools of the same rank, (b) *Provveditori*, (c) Heads of secondary schools situated in another district, (d) Ordinary teachers of the second grade of secondary schools having taught at least ten years and teaching in schools outside of the district for which they are appointed inspectors. *a* and *b* inspect second-grade secondary schools, and *c* and *d* first. Inspections are made according to need, but there is a regular inspection in each school for each subject once in five years. The purpose of the inspection is to ascertain whether the course of study has been followed and to report on textbooks and to superintend the discipline and the method of teaching; to make, according to the results of the inspection, the needed recommendations for the final appointment or dismissal, approval or censure of teachers, to give any information required by the Ministry concerning any teacher. At the end of each school year the inspectors of each district meet and compile a collective report in which are stated the conditions and needs of the schools.

At the Ministry there are ten inspectors for secondary schools; six are permanent and are appointed from among officers of classes (a), (b), and (c). Four are appointed yearly and reappointed for not more than five years. The central inspectors, besides special duties that may be assigned to them from time to time, compile the general program of inspections to be submitted to the Minister, coordinate the results of inspections; recommend to the Minister the needed changes on the basis of those results, propose to the Minister extraordinary inspections, general and particular inquiries and, if needed, carry them out; promote investigations relating to course of study and method of instruction; present to the Minister yearly a general report on secondary schools.

**Fine Arts and Music Schools.** -- Government fine arts and music schools are under the direction of the Minister of Public Instruction. They have not a uniform organization and vary in importance in every respect. The number of fine arts government schools was thirteen in 1901-1902 with 2433 pupils (2137 boys and 296 girls). The non-government schools were thirteen with 1625 pupils (1363 boys and 262 girls). The former had 167 teachers, the latter 65.

The government music schools were five in number with 952 pupils (353 boys and 419 girls), the non-government 51, with 4431 pupils (3408 boys and 1023 girls). The number of teachers in the former was 146, in the latter 395.

**Agricultural, Industrial, and Commercial Schools.** -- Notwithstanding article 1 of the Casati Act, which says all schools are under the Ministry of Public Instruction a great number of

schools have been established under the supervision of the Ministry of Agriculture, Industry, and Commerce. They are practical schools of agriculture, commerce etc.

The schools of agriculture are regulated under the act of June 6, 1885, No. 3141. They are established at the suggestion of local authority (*comuni*, province, etc.) which pay two fifths of the expenses besides providing an experimental farm, while the state pays three fifths. Each school is managed by a committee whose members are appointed partly by the government and partly by the local bodies sharing in the expenses. They are classified as either practical or special schools. The course of study of the practical schools covers three years, and includes Italian, history, geography, arithmetic, geometry, surveying, drawing, accounting, bookkeeping, penmanship, natural and physical sciences, agriculture and related industries. Some have a fourth year of practical studies.

To be admitted, boys must have passed the examination for admission to the fourth class (year) of the elementary schools, but though that examination is usually passed at the age of nine to ten, boys are not admitted to the agricultural schools until they are at least fourteen and not after they are seventeen. The boys may board on the school farm. The staff of each school includes, as a rule, a director, a vice-director, an elementary school teacher and an assistant, besides extraordinary teachers for special subjects.

Special schools of agriculture are of two grades. Those of the first grade are organized like the practical schools with this difference, that instead of agriculture in general, particular branches are offered, *i.e.* dairying at Reggio, horticulture at Florence, vine raising and wine making at four schools. The four of the second grade, all for vine raising and wine making, are in their plan of studies similar to sections of *istituti tecnici*. Boys are admitted if they have passed the final examination of a practical school or a special school of the first grade or of a *scuola tecnica*.

Commercial and industrial schools are governed by the by-laws of June 1, 1908, No. 187. They are established on the suggestion of local bodies (*comuni*, province, chambers of commerce, etc.), which share the expense, the Minister of Agriculture contributing within the limits of the total appropriation for that purpose. These schools are divided into: (a) industrial schools, *i.e.* manual training schools; (b) artistic-industrial schools; (c) commercial schools; (d) schools for girls.

There are two grades of each class corresponding to the first and second grade of the secondary schools. Their plan of studies varies greatly, ranging from schools of drawing with one teacher to a school fully equipped like the *scuola industriale* of Vicenza or like the *scuole medie di commercio*, which correspond in all

respects to a section of *istituto tecnico*. In the majority of these schools the teaching takes place on evenings and Sundays. The total number of these schools, which receive grants from the government, was 310, with more than 47,000 pupils in 1903-1904. The total expense for that year was more than 3,000,000 lire, of which about 700,000 was paid by the state and more than 800,000 by the *comuni*. The number of teachers was over 2000. There were 427 schools, which did not receive any grant from the government.

All these agricultural, commercial, and industrial schools are under the supervision of a special committee, the *Consiglio superiore dell'insegnamento, agrario, industriale e commerciale* which was established in 1907 by the amalgamation of two previously existing, one for agricultural and the other for commercial and industrial schools. There is also a body of inspectors, and the Minister may appoint other persons, whom he thinks suitable, for special inspections.

There are also three mining schools which rank as secondary schools of the second grade.

**Boarding Schools** — The schools referred to above are day schools. Boarding schools are for the most part private institutions. There are a few government institutions (those for boys called *convitti nazionali*), where pupils may board and follow the courses at the public secondary schools or the elementary schools.

**Reform.** — Ever since the promulgation of the Casati act the reform of the secondary schools has caused much discussion. Since then some changes have been introduced in the plan of studies by one Minister and changes in the opposite direction by another. Many bills have been introduced into Parliament for a general reform, but none has become a law.

In 1906 a Royal Commission was appointed to investigate the whole subject of secondary education. They have issued a report including a proposal for a new organization. The idea of a single secondary school for the first grade, which not long ago obtained, has been abandoned, and they propose for the first grade:

(a) A three years' *ginnasio* for those who intend to pass to the *liceo* and then to the universities, the plan of studies including Italian, French, history, geography, psychological education, elements of mathematics and natural sciences, drawing. Boys and girls will be admitted if they are ten years old and have passed the *maturità* examination. (b) A *scuola tecnica* preparing for the professional school of the second grade. Boys and girls will be admitted if they have passed the *maturità* examination. (c) A *scuola complementare* for those who do not intend to pass to schools of the second order. Admission to be gained after the sixth year of study in the elementary schools.

For the second grade they propose: (a) A *liceo* with a five-year course for those who intend to pass to the university. They propose

three different kinds of *liceo*: (1) classical *liceo* with Latin, Greek, and French; (2) modern *liceo* with Latin, French, and English or German; (3) scientific *liceo* without Latin, which would take the place of the physico-mathematical section of the *istituto tecnico* (b) Professional schools taking the place of the professional sections of the *istituto tecnico* and of the special schools of the second grade now under the Ministry of Agriculture.

**Higher Education.**—Higher education is given at the universities (*università*) and at other institutions the majority of which are designated as schools (*scuole*) or institutes (*istituti*). Some of these institutions are connected with universities, others are entirely independent. If under the control of the government, the universities are called *regie*; if under local bodies, *libere*. All universities are governed by the same laws and by-laws, the other institutions by special laws and by-laws.

The faculties, all of which are found in the largest universities, are: (1) law, (2) medicine and surgery, (3) mathematical, physical, and natural sciences, (4) belles-lettres and philosophy. In addition, there are schools in the following subjects: pharmacy, engineering, veterinary science, agriculture, commerce and social sciences, oriental languages, midwifery; and courses for notaries and attorneys, for secondary and elementary school teachers, and schools for women. All commercial schools, the agricultural schools at Milan, Portici, and Perugia, and the forestry school at Vallombrosa are under the Ministry of Agriculture, Industry, and Commerce; all other institutions are under the Ministry of Public Instruction.

The following is a list of institutions with the date of foundation, faculties, and number of students in 1910-1911.

**Maintenance** — The expenses in the various institutions are borne by the State, local bodies contributing in different ways. By act of 1862 the universities of Genoa, Parma, Modena, Siena, Macerata, Cagliari, Sassari, Messina, and Catania were made universities of the second rank. To have them raised to first rank local bodies agreed to pay to the State the difference involved in the salaries of teachers, and in a few cases to have the faculties completed. Local bodies of other cities contribute funds to establish schools either in connection with universities or as independent institutions. These contributions are of a permanent character. Other extraordinary payments have been made for new buildings or other extraordinary expenses. Free universities are supported entirely by local bodies, except Urbino, which receives a small subsidy from the State. The Institute of Social Sciences of Florence and the Commercial University of Milan are supported by private gifts.

To all other commercial schools, to the Poly-

technic School at Turin, the School of Naval Engineering at Genoa, the Higher Institute of Florence, and the Clinical Institute at Milan, the State contributes a fixed sum. All these institutions are administered by special boards in which local bodies are represented, but professors are appointed by royal decree or ministerial selection. The School for Oriental Languages at Naples has a patrimony of its own administered by the Minister of Public Instruction; also the Institute of Agriculture of Perugia.

The general by-laws regulating the universities and some of the other institutions are those of Aug 21, 1905, No 638.

**Administration** — For each university there are the following: (a) a principal (*Rettore*); (b) an academic council (*Consiglio accademico*); (c) a general assembly of professors (*Assemblea generale dei professori*). For each faculty: (a) a dean (*Preside*); (b) a council of professors (*Consiglio di facoltà*). Special schools have, as a rule, an organization like the faculties; the head, however, is usually called director (*Direttore*).

**Rector.** — The *Rettore* is chosen by the king from three ordinary professors nominated by the general assembly of professors; he is appointed annually and may be reappointed. In Naples he is elected by the professors from three ordinary professors selected from the various faculties in turn; the election has to be approved by the Minister. The *Rettore* is appointed for two years. He is the chairman of the academic council and the assembly of professors; represents the university on all occasions, confers degrees in the name of the king; communicates his decisions, those of the academic council, the faculties councils, the general assembly of professors and the Minister to all concerned; sees that all by-laws are adhered to, looks after the administration by means of the secretary of the university and other employees; inspects the university library and all institutions belonging to the university; regulates the discipline of professors, students, and employees; and compiles a yearly report to the Minister, and grants leave of absence.

**Councils.** — The academic council is composed of the following: (a) the *Rettore* in office, (b) the retiring *Rettore*; (c) the deans of the faculties; (d) the retiring deans; (e) the director of the schools connected with the university. Among other functions the council (a) grants scholarships and makes proposals for state scholarships; (b) gives its advice on changes relating to the university regulations or any subjects submitted by the *Rettore* or the Minister, (c) fixes the time schedule for classes; (d) grants dispensation from payment of fees; (e) decides upon the disposal of funds.

The general assembly of professors, both ordinary and extraordinary, gives its advice on reforms in universities, and nominates the three

The totals do not include students following the special course for elementary school teachers

<sup>1</sup> Incomplete.

professors whose names are to be submitted to the king for the appointment of the *Rettore*. For this latter purpose representatives of private professors take part, two for each faculty or school.

The dean represents the faculty on all occasions and is the chairman of its councils, acts as intermediary between the faculties and the rector; submits a yearly report from the faculty to the *Rettore* concerning the work and examinations, with his remarks. The dean is appointed for three years and may be re-appointed.

The council of ordinary and extraordinary professors of the faculty suggests to the students the order of studies to be pursued, co-ordinates the syllabi submitted by the professors, compiles the schedules for classes proposes new courses, designates the persons fitted to give such courses, and those who may temporarily fill vacant chairs, and proposes the means of permanently filling such vacancies. The council submits to the academic council proposals for changes in the regulations, and submits the names of three professors from whom the king will appoint the dean. The council meets once every two months and may meet extraordinarily when five professors demand it.

*Professors* — Professors are ordinary (*ordinari*), extraordinary with a permanent appointment (*straordinari stabili*), extraordinary (*straordinari*), *incaricati*, and private professors (*liberi docenti*). The appointments and transfers of ordinary and extraordinary professors are regulated by the acts of 1904 and 1907. The provisions of these acts apply to all Royal universities and to some of the schools, and are also followed in the main for the others, although their provisions do not apply to them.

The Minister has the right, according to the Casati act, to submit to the king the names of men of exceptional merits for appointment as ordinary professors. This, however, very seldom happens, and both ordinary and extraordinary professors are, as a rule, appointed by selection from applicants according to their qualifications, which are passed upon by a committee of professors. Ordinary professors are appointed by royal decree. An extraordinary professor is appointed for the first time by the Minister for one year, after which he is appointed for a second year and then for a third in consultation with the faculty. When he has been reappointed twice and has taught three successive years, he is made, by royal decree, a permanent extraordinary professor (*straordinario stabile*) after the advice of the higher council has been heard. In engineering schools extraordinary professors may be appointed by the Minister, regardless of the usual formalities. An extraordinary professor having a permanent position may be promoted to ordinary upon the favorable report of a com-

mittee appointed in the same way as those who pass upon the applicants for new positions.

*Incaricati* are appointed by the Minister on the suggestion of the faculty in the case of obligatory courses. For complementary courses the advice of the higher council is also taken. Ordinary and extraordinary professors, those who have been recognized fit to hold chairs as such, those who have occupied chairs, and private professors, may have a temporary appointment as *Incaricato*. Such an appointment lasts not more than one year, but may be renewed.

Besides official professors there are private teachers. To be permitted to teach, one must file an application with the Minister, stating what subjects and at what institutions he wishes to teach. He has to pass a special examination which consists of (a) a written dissertation on a subject chosen by the examining committee; (b) an oral examination upon that subject and on the science which he intends to teach; (c) a lesson. Applicants, however, who have given proofs of a thorough knowledge of the subject may be excused from the examination or from parts (a) and (b). Such applicants must have published at least one memoir on the subject they desire to teach.

The universities of Turin, Genoa, Sassari, and Cagliari have also *Dottori aggregati*, which correspond to the French *agrégés*.

*Salaries* — By an act of 1909 the salary of ordinary professors has been raised from a minimum of 5000 to a minimum of 7000 lire, with periodic increases of 750 lire every five years up to 10,000 lire, and that of extraordinary professors from a minimum of 3000 to 4500 lire with periodic increases for the *stabili* of 450 lire up to 7000. *Incaricati* receive a fee of 30 lire per lesson, if they are ordinary or extraordinary professors, they receive 2000 lire a year, if they are not official professors. This increase applies to all Royal universities and other institutions with the exceptions noted below. The same act fixed the salaries of professors of higher institutes for women at 5000 lire, if ordinary, with increases of 500 lire every five years up to 7000 lire, and at 3500, if extraordinary, with increases of 350 every five years up to 5000 lire. Salaries of professors at the university schools are lower.

The salaries of the professors of the Higher Schools of Commerce, of the School for Oriental Languages, and of the Institute of Forestry have not been changed and are as a rule 5000 lire, with periodical increases of 500 for ordinary, 3000 for extraordinary, and 1200 for *incaricati*.

The Casati act fixed the number of ordinary and extraordinary professors in each Faculty or school, but the act of 1909 has done away with such provision and fixed the total number of professors at Royal universities and other government institutions under the Ministry of Public Instruction, except institutes for women,

## ITALY

oriental institutes, and university schools, at 861 ordinary professors and 215 ordinary professors of fundamental subjects and thirty-eight ordinary and twenty-seven extraordinary professors of complementary subjects. New chairs can be established in these institutions only by law, with the exception that those institutions which have a special administration to which the State contributes a fixed sum may change the number of ordinary and extraordinary professors provided no higher charge will result to the State. The number of ordinary and extraordinary professors at the other institutions is separately fixed at each of them. For the *incaricati* compensation a lump sum is appropriated.

A certain number of assistants are attached to universities and schools. The total attached to Royal universities and other government institutions under the Ministry of Public Instruction, except institutes for women, oriental institutes, and university schools, is 1054, and the salaries vary from 1500 to 2400 lire a year. To Royal observatories also are attached assistants, thirty in all, including the observatories of Milan, Naples, and Rome not attached to universities, their salaries varying from 2000 to 5700 lire.

**Fees** — Fees were considerably raised by an act of 1903. For the whole course they amount to 1275 lire for the faculty of medicine, 1185 for the faculty of law, 1150 for the engineering schools, 805 for the faculties of sciences and letters, from 950 to 510 for the school of pharmacy, 705 for the courses for notaries and attorneys, 500 for the schools of agriculture, and 510 for the school of veterinary surgery, 110 for the courses for secondary teachers (above faculty fees). Examination fees are included in the above totals and go to the examiners. The increase of revenue, due to the raising of the fees, is applied partly by the State, partly by the universities and schools to increase salaries of assistants, to establish scholarships, to grants for laboratories and libraries.

Those who wish to be authorized to teach privately at universities must pay a fee of 250 lire, and if they wish to transfer from one university to another, they must pay a fee of 100 lire.

Numerous scholarships are granted by the *comuni*, *province*, state and endowed institutions. Among others the State grants every year nine scholarships to be held abroad.

**Students.** — In order to matriculate as a regular student in a university it is necessary to have the diploma granted to those who have passed the final examination of a *liceo* (or have been excused from it) or, for the faculty of sciences and the schools, that of the physico-mathematical section of a technical institute. The diplomas of all sections of the technical institute admit to the schools of pharmacy, veterinary science, and agriculture. The diplo-

## ITALY

mas of special (secondary) agricultural schools admit to the latter, those of the (secondary) professional schools of the second grade admit to the corresponding schools of university standing.

Besides regular students, there are *uditori* (auditors) who pursue certain courses but cannot become candidates for a degree. No condition is required to matriculate as *uditori*. All courses are open to the public.

No colleges in the English sense exist at any of the universities. There are, however, the *Collegio Ghislieri* at Pavia, where those students belonging to the Lombard provinces who gain scholarships board, and a boarding college annexed to the *Scuola normale superiore* of Pisa.

The school year begins in the middle of October and ends in July. Work begins early in November and ends about the 20th of June.

**Degrees** — The faculties of science and letters and the school of pharmacy under the 1906 regulations granted a preliminary degree called *licenza* after two years of study, which was required in order to enter the third year of study, but a recent decree has removed such requirement. After he has passed all special examinations, the student is admitted at the end of the course of study or at any time afterwards to take the examination for the doctor's degree. Such examination consists of (a) a written dissertation on a subject chosen by the student, (b) an oral discussion of the dissertation and of two out of three subjects chosen by him. A doctor's degree is required not only for the professions (physician, lawyer, teacher in secondary school, etc.) but also to enter the highest grade clerkships in the government service in all branches.

The length of the courses in the various faculties is as follows —

**Law** four years' course leading to the doctor's degree (*dottore in giurisprudenza*), also two special courses of two years each for notaries and attorneys.

**Medicine** six years' course leading to the degree of doctor of medicine and surgery. A two years' course for midwives is given at all faculties of medicine.

**Sciences** four years' courses leading to the degrees of doctor of pure mathematics, physics, chemistry, and natural sciences. The first two years are prerequisite for schools of engineering. Courses for secondary school teachers.

**Belles-Lettres and Philosophy** four years' course leading to the doctor of belles-lettres, and doctor of philosophy (for which courses in the sciences and experimental psychology are obligatory). Special two years' course for elementary school teachers.

**Pharmacy** four years' course leading to a diploma of pharmacy, five years' course leading to the degree of doctor of chemistry and pharmacy.

**Veterinary Science** four years' course leading to the doctor's degree (*dottore in zoovetina*).

**Agriculture** four years' course leading to the degree of doctor of agricultural sciences. Special teachers' diplomas are given to holders of this degree, on completing additional courses at Milan and Portici.

**Commerce** three or four years' courses leading to the doctor's degree in sciences applied to commerce. Courses for secondary school teachers.

**Engineering** three years beyond the two preparatory years in the faculty of sciences, or at the special school

The total number of students has grown from 22,515 in 1893-1894 to 27,302 in 1905-1906 or from about 72 per 100,000 inhabitants to over 81. In 1910-1911 the total number of regular students at all universities (Royal and Free) and all schools under the Ministry of Public Instruction (the institute for oriental languages excepted) was 26,372, that of students following only some courses 212. In 1909-1910 these institutions granted 2903 doctor's degrees, 485 engineering diplomas, 494 pharmacist diplomas, and 702 other minor diplomas.

**Higher Institutes for Women** — These institutions offer to those who have completed the course in normal schools special four years' courses, at the end of which the students are granted diplomas authorizing them to teach Italian or history and geography or pedagogy and ethics or foreign languages in all secondary schools for girls. The first two years are common to all and include algebra and geometry, physics, chemistry, natural history and hygiene, history of Italian literature, geography, political history, psychology, logic, and ethics, French language and literature, English or German language and literature, drawing. For the third and fourth year all pupils follow courses of history of Italian literature; political history, French language and literature; German or English language and literature; civics and political economy, history of art; drawing, and other special courses, according to the diploma they wish to take and practice in the subjects of the diplomas.

Besides the two government institutes at Rome and Florence there is a private one in Naples whose diplomas are recognized as equivalent to those of the former.

**Special Schools** — The old Chinese college established in 1727 was reorganized in 1888 into a School for Oriental Languages. A general course is now offered in the geography, religion, legislation, and commerce of oriental countries, and special courses in Turkish, Arabic, Chinese, Japanese, Persian, Amharic, Modern Greek, Albanese, English, Russian.

As will be seen, there is no provision for university teaching of theology, fine arts, and music. For the last two some courses at the secondary schools are of a higher grade, and the State offers some scholarships every year to be held at Rome for music, fine arts, and history of ancient and medieval art. At three engineering schools there are courses for architects, but with very few pupils, and studies more scientific than artistic. Bills introduced for the establishment of schools of architecture have failed. The faculties of Catholic theology were suppressed by act of 1873. Such teaching is now carried on at the seminaries, and, in Rome, at some other institutions. For Protestant theology there is a Waldensian school at Florence.

**Other Educational Institutions** — Not treated in the foregoing account are: (a)

*università popolari* (as they do not offer regular courses of study, but only university extension lectures); (b) military schools, under the Ministry of War (see MILITARY EDUCATION); (c) naval schools, under the Ministry of the Navy (see NAVAL EDUCATION); (d) school for officers in the customs service, under the Ministry of Finance, (e) postal-telegraph institute under the Ministry of Post and Telegraph; (f) school for medal artists (*scuola dell' arte della medaglia*), connected with the Mint; (g) reform schools (*risformatori*), under the Ministry of the Interior; (h) Italian schools abroad, under the Ministry of Foreign Affairs; (i) courses on agriculture (*cattedre ambulanti d'agricoltura*) and other courses connected with agricultural experiment stations under the Ministry of Agriculture, Industry, and Commerce; (j) the school for forest guards at Citaducale; (k) courses on paleography and diplomatics at state archives, under the Ministry of the Interior.

**Reform** — Many bills dealing with university reform have been introduced in Parliament, but as for secondary education none has passed. Only those dealing with appointment, transfer, and salary of professors have become acts. In 1912 two bills were presented to Parliament reorganizing the higher schools of commerce, professional schools under the Ministry of Agriculture, etc., and transferring the school of forestry at Vallombrosa, and amalgamating it with the Higher Institute at Florence. **IVES, ELI** (1779-1861) — Author of textbooks and medical writer, was graduated at Yale College in 1799. He was principal of the Hopkins Grammar School (q.v.) at New Haven, one of the organizers of the medical department of Yale College; professor at Yale (1813-1861), and the author of several textbooks and numerous papers on medical subjects.

W. S. M.

See YALE UNIVERSITY.

**JACKMAN, WILBUR SAMUEL** (1855-1907) — Leader in the nature study move-

ment (*q.v.*) and educational writer, was born at Mechanicstown, O. He graduated at the California (Pa.) State Normal School in 1877; studied two years at Alleghany College, and graduated at Harvard University in 1884. He was instructor of science in the Pittsburgh High School from 1884 to 1889, when he was engaged by Francis W. Parker (*q.v.*) to take charge of the science work in the Cook County (now Chicago) Normal School. Here he developed the lines of nature study teaching which became the general practice in elementary schools. In 1899, when the Chicago Institute was organized, he accepted the post of head of the science department, and when this was later merged into the School of Education of the University of Chicago, he became the professor of natural science. He was dean of the College of Education from 1901 to 1904, and principal of the University Elementary School from the latter date until his death. His published works include *Nature Study for Common Schools* (1891), *Number Work in Nature Study* (1893), *Nature Study Record* (1895), *Nature Study for Grammar Grades* (1898), and numerous papers on the place of nature study in education. He was also editor of the *Elementary School Teacher*. W. S. M.

**JACKSON, ABNER** (1811-1874) — Fourth president of Hobart College, was graduated from Trinity (then Washington) College in 1837. He was tutor and professor at Trinity (1838-1858) and was president of Hobart College (1858-1867). Author of several papers on education. W. S. M.

**JACKSON COLLEGE FOR WOMEN** — See TUFTS COLLEGE

**JACKSON, CYRIL** (1746-1819) — Dean of Christ Church, Oxford, born in Yorkshire and educated at the Manchester Grammar School and at Westminster School under Dr. Markham (*q.v.*). He entered Christ Church, Oxford, in 1764, graduated B.A. in 1768. After acting as sub-preceptor to the sons of George III under Dr. Markham, he took holy orders. He became Canon of Christ Church in 1779 and Dean in 1783, in which position he attained great popularity with the students in spite of the strict enforcement of discipline. He attached importance to the college examinations and encouraged his students to compete for prizes and exhibitions. He assisted in framing the Public Examination Statute at Oxford which was put into practice in 1802, many Christ Church students took high rank in the

Oxford examinations. He resigned in 1809. Jackson was a man of great intellectual ability, was considered a good classical scholar, had a knowledge of mathematics, botany, and architecture, and became a Fellow of the Royal Society. Many of his students attained positions of eminence in politics, the chief among them being Sir Robert Peel.

**JACKSON, EDWARD PAYSON** (1840-1905). — Author and teacher, born at Erzerum, Turkey; educated at Amherst College; master in the Boston Latin School (1877-1905), and author of several geographical works and numerous scientific articles and monographs. W. S. M.

**JACKSON, HERMAN MERILL** (1815-1868) — College president and educational author, was graduated from Wesleyan University in 1839. He was professor at St. Charles, Mo., College (1839-1842), Augusta College, Ky. (1842-1844), Ohio Wesleyan University (1844-1850), Dickinson College (1850-1860), and president of Dickinson College (1860-1868). He was author of Latin textbooks and essays on education. W. S. M.

**JACKSON, SHELDON** (1834-1909) — Missionary educator and organizer of schools in Alaska (*q.v.*), graduated at Union College in 1855 and at the Princeton Theological Seminary in 1858. He engaged in missionary work among the American Indians (1858-1864); served as principal of the Rochester Female Institute (1864-1869), was special agent of the government to select Indian children for the schools at Carlisle and Hampton (*q.v.*), and organized mission schools in the Northwest (1869-1877), organized the educational work of Alaska in 1877, and was superintendent of schools and general agent of education in Alaska (1877-1900). He published the *North Star* at Sitka (1887-1893); organized the Alaskan Society of Natural History and Ethnology (1887), and published numerous reports on education in Alaska. He inaugurated the reindeer service in Alaska in 1892. W. S. M.

**JACOBI, MARY PUTNAM** (1842-1906). — Educational writer and physician, received her professional education in the Philadelphia Woman's Medical College and the Ecole de Médecine of Paris. She was professor in the Woman's Medical College of New York and the New York Post-Graduate Medical School. She wrote *Studies in Primary Education*, *Adolescent Girls*, and numerous papers on educational and medical subjects. W. S. M.

**JACOTOT, JEAN JOSEPH** (1770-1840).

— A French mathematician and teacher, who originated a famous "universal" method in education. In his diversified career he was professor of Latin and Greek literature, subsequently of mathematics, and Roman law, entered the army, eventually rising to rank of captain of artillery; was a member of the Chamber of Deputies, later became lecturer on French language and literature at the University of Louvain, and director of the military school of Belgium. The extremely diversified character of his life and interests undoubtedly led to one of his educational fallacies that "all human beings are equally capable of learning." If this be sound, it forces one to the conclusion that everybody can be proficient in anything to which he turns his attention, in which case there is really little justification for believing in the selective function of the school. Jacotot's educational principles are set forth in paradoxical fashion in his *Enseignement universel* (Louvain, 1822). "Every man can teach, and even teach what he himself does not know." Jacotot's own success in teaching French to Flemish students at the University of Louvain, while he himself did not know a word of the language of his pupils, gave some color to his assertion. He did this by means of books printed in French and Flemish in parallel columns. The fact that his students learned though he did not teach them apparently supported another one of his contentions "One can instruct himself all alone." *Tout est dans tout* (All is in all) is probably the most familiar of all his paradoxes. The corollary, "Know one thing thoroughly and relate everything else to that," throws considerable light upon the earlier axiom. In other words, no bit of learning exists by itself, but bears a direct relation to a large number of related knowledge fields. In practical application of this axiom, Jacotot took Fénelon's *Télémaque* as a point of departure, requiring that six books of that classic be committed to memory by the pupil. Not only did this, with all the commentaries, immensely broaden the field of the pupil's knowledge, but furthermore the method of work necessary to assimilate this carried over very materially in attacking other problems. His universal method consisted of four steps: (1) learn something as closely related as possible to the subject in hand, but learn it so thoroughly that it will be constantly ready for use, (2) repeat that something unceasingly; (3) reflect upon that work done until it no longer rests upon the surface of the memory mass, so to speak, but until it has sunk down deep and has become a real part of the individual's mental stuff; (4) verify or test other facts, rules, generalizations, etc., and measure them all in terms of what you already know. Concrete applications of this method will be found in each of the authorities cited below. In spite of the vagarious character of his paradoxes, Jacotot's generaliza-

tions did contain some germs of truth, but stated in the sweeping form in which he expressed them, they had little practical value. This is particularly true of his notion that whatever became really assimilated was that which the individual had worked out for himself, and not what somebody had told him; and the very broad suggestion of the principle of correlation which is found in his "all in all" axiom. Nevertheless, Jacotot enjoys a far greater reputation in Germany than in his native country, and one which unquestionably overestimates his positive influence upon educational thought and educational practice. His chief works were: *Enseignement universel, Langue maternelle* (Louvain, 1822), *Musique, Dessin et Peinture* (Louvain, 1824); *Mathématiques* (Louvain, 1827); *Langues étrangères* (Louvain, 1828); *Droit et Philosophie panécastiques* (Paris, 1837). See also the *Journal de l'Émancipation intellectuel*, published by his two sons  
F. E. F.

**JACQUES, JABEZ ROBERT** (1828-1892)

— College president, was graduated from Genesee College in 1854; instructor in academies in New York, 1854-1858; professor in Rochester Collegiate Institute, 1862-1865, and Illinois Wesleyan University, 1865-1875, president of Albert College, Canada, 1875-1885, and of Hedding College, Illinois, 1886-1892. Author of *Study of Classical Languages* and sermons on education  
W. S. M.

**JAHN, FRIEDRICH LUDWIG** (1778-

1852) — The father of German gymnastics, familiarly known to German gymnasts as *Turnvater Jahn*. He was born in Lanz, Prussia, the son of a country pastor. The first thirteen years of his life were spent at home, where he learned to read the Bible and studied history, geography, and the German language under the direction of his parents. He early manifested keen interest in outdoor life and all sorts of physical activities; he learned to ride and swim and was very fond of walking, climbing, jumping, and running. In 1791 Jahn entered the Gymnasium at Salzwedel, and in 1804 left to enter the Gymnasium zum Grauen Kloster in Berlin. His independent and restless spirit led him into frequent conflicts with teachers and fellow pupils. His university career was varied and stormy. He spent five years in Halle, one year at Greifswald, and brief

periods at Göttingen and Jena. In each of these universities he carried on strenuous campaigns of opposition against the student clubs or *Lansmannschaften*. In 1806 he joined the army and wandered through various German states until July, 1807, when the Treaty of Tilsit was signed.

The next two years were spent in literary work at Jena, and in 1809, Jahn went to Berlin where he taught history, German, and mathematics in the *Gymnasium zum Grauen Kloster*, the same school from which he had run away fifteen years before. He took the boys to the *Hasenheide*, on Wednesday and Saturday afternoons, and taught them games, running, jumping, and wrestling. The exercises were so popular with the boys that Jahn continued to teach them indoors during the winter months.

In the spring of 1811 Jahn established the first regular *Turnplatz* at the *Hasenheide*, and from this time on the terms *Turnkunst*, *turnen*, *Turnhalle* became familiar. This was the real beginning of his life's work, the founding of the great movement for popular gymnastics in Germany. An important feature of the activities was the singing of patriotic songs.

In 1813 Jahn responded to the first call for soldiers in the War of Liberation. He returned to Berlin after the war, and in 1817 received the honorary degree of Doctor of Philosophy from the universities of Jena and Kiel, in recognition of his services to the fatherland in time of need, his stimulating influence on the young, his power as a public speaker, and his efforts in behalf of the German language. As the result of his agitation in favor of German nationality, he was arrested in July, 1819, on suspicion of "secret and most treasonable association." From this time until 1840 Jahn was forbidden to live "in Berlin or within a radius of ten miles from the capital, or in any city containing a university or higher school for boys." This restriction was removed when Frederick William IV ascended to the throne, and Jahn was decorated with the Iron Cross. In his last address delivered about 1848, he closed with these words: "Germany united was the dream of my childhood, the morning glow of my youth, the sunshine of middle life, and it is now the evening star which beckons me to everlasting rest." His declining years were spent in poverty and obscurity, and he died at Freyburg, after a brief illness, Oct. 15, 1852.

*Turnvater* Jahn is still held in loyal and grateful remembrance, as the apostle of German unity and the man who gave to the German people a love for gymnastics. Monuments have been erected to him in Berlin, Lanz, Freyburg, and other places. Jahn's most important writings are the following:—

*Über die Beförderung des Patriotismus im Preussischen Reiche* (Halle, 1800); *Bereicherung des Hochdeutschen Sprachschatzes versucht im Gebiete der Sinneverwandtschaft, ein Nachtrag zu Adelung's und eine Nachlese zu*

*Eberhard's Wörterbuch* (Leipzig, 1806), *Deutsches Volksthum* (Lübeck, 1810), *Die Deutsche Turnkunst zur Einrichtung der Turnplätze, dargestellt von Friederich Ludwig Jahn und Ernst Eiselen.* (Berlin, 1816.) G. L. M.

**JAMAICA, EDUCATION IN.**—Jamaica was seized by the English in 1655, and their possession of the island and the attached Turks and Caicos islands was confirmed by the treaty of Madrid in 1670. The administration is committed to a resident governor appointed by the crown, and a legislative council which is partly formed by election. The population is estimated at 862,000, of whom the blacks constitute 56 per cent and mixed races 18 per cent. The moral and intellectual condition of the people early excited missionary interest, it was not, however, until the nineteenth century that systematic efforts were made for their improvement by religious societies and philanthropists. Between 1820 and 1834 forty schools were established for the instruction of slaves and seven for free people. In the latter year slavery was abolished in the island, and in the following year (1835) Government allowed £50,000 to be used in building school-houses. Soon after, the Mico bequest of £1000 which was made 100 years before and had increased in the interim to £110,000, became available for the education of the former slaves. Under the double stimulus of government and private funds, schools for the people multiplied for a time, but the interest declined and for thirty years little progress was made. In 1865 the cause was revived and several measures were adopted by the Legislature, looking to the improvement of the schools. Competitive examinations were ordered for schoolmasters, and in 1867 the grant-in-aid system was introduced after the English plan, and thus the existing elementary schools were brought under a measure of government supervision. Several endowed schools, following the model of the English endowed or grammar school, had also been established for the children of the privileged or ruling class in Jamaica, and in 1879 a special commission was appointed to inquire into the condition of this class of school and to make recommendations for their further conduct. A few years later, 1885, a commission of inquiry was appointed for the entire system of elementary education and as a result, chiefly,

of the investigations of that body, a new organization of the work was effected.

In accordance with the recommendations of the commission, the legislative council in 1892 created a central board advisory to the Education Department in respect to elementary education, authorized the levy of a local school tax, and provided for a special grant in lieu of fees for schools remitting the same. The legal age for school attendance was fixed at six to fourteen years of age, and the governor was authorized to enact compulsory attendance laws at his discretion. A second commission appointed in 1898 made a very thorough investigation of the entire educational system, and their recommendations as regards elementary schools, as far as practicable, were embodied in the code of regulations issued by the Education Department in 1900.

The schools are either public, *i.e.* supported and managed by the government, or voluntary (chiefly under denominational management). Both classes of schools share on the same terms in the grant which is distributed on the basis of the results of the annual examinations and the inspector's report as to the general condition of the school, together with the number and qualifications of the teachers. There is no color line in the public schools, but separate schools are allowed where required. White children are generally sent to private schools or are instructed at home by tutors.

For the latest year reported (1909-1910) the number of elementary schools was 693, with an enrollment of 89,902 pupils and an average attendance of 57,849, or 64 per cent of the enrollment. The government grant for the schools amounted to £47,399 (\$228,359) equivalent to \$3.94 per capita of average attendance. The obligatory program for the elementary schools includes besides the three elementary branches, elementary science as related to agriculture and handicraft. Optional branches for which grants are allowed are Scripture lessons, geography and history, English language, geometric drawing, and singing. Special grants are allowed for drawing and needlework. The government bears part of the expenditure for five industrial schools in which provision is made for orphan or abandoned children. The three training colleges for women were attended by sixty-one students and the single training college for men, by sixty-eight students.

For secondary education there are two schools aided by the government, enrolling in 1910 a total of 133 pupils, and several unassisted, endowed schools. These schools all prepare students for the Cambridge Local Examinations, Senior, Junior, and Preliminary, which are held at seven centers in the Island. University College, founded in 1888 as an extension of the Jamaica High School, prepares students for the London University examinations. A Rhodes scholarship of the

value of \$1500, tenable for three years, is assigned to Jamaica.

Two noteworthy evidences of progress are dwelt upon in the recent official reports; *viz.* the multiplication of school gardens, and the excellent condition of the schools in Kingston, the capital city. The number of schools to which school gardens are attached is 361, with an attendance of 24,000 children of an age to benefit by the practical training thus afforded. The sum of \$2500 was appropriated in aid of this work in 1910, and four prizes ranging in value from \$5 to \$20 offered for competition in each of the schools. A special course in agriculture is given at Kingston for the benefit of teachers. Provision has been made at seven centers for advanced manual training, and it is proposed to establish at Kingston a school of technology. The system of elementary education with its special extensions is under the general supervision of the Superintending Inspector, who is assisted by a corps of inspectors, one for each of the seven school districts. The majority of these officials are graduates of English universities. The most urgent need of the system is provision for adequate salaries and a more certain tenure for the teachers.

**JAMES, WILLIAM** (1842-1910.) — Probably the most eminent American philosopher and psychologist, was the son of a theologian. The account of his training and of the development of his career and influence as teacher and author, as psychologist and philosopher, is one of the most romantic known to biography. Owing in part to the foreign residence of his father, and in part to his own varied interests, his higher education extended over a period of ten years. It included a year at the University of Geneva, one year as a student of art under Hunt at Newport, two years in the Lawrence Scientific School, devoted mostly to anatomy and chemistry, two years in the Medical School of Harvard University, a year in Brazil with Agassiz, the naturalist, one year in Berlin, pursuing physiology, and finally a return to Harvard, for further work in zoology, where he received the M.D. degree in 1869.

During thirty-five years he was a teacher in this university. After giving instruction in physiology and anatomy seven years, he transferred his work to philosophy for nine years, followed by a nearly equal period as a teacher of psychology. The last decade of active teaching found him again a professor of philosophy. He was brilliant, influential, ever ready to help young minds "find them-

A GROUP OF MODERN UNIVERSITY EDUCATORS.

selves." He was also a lecturer at Columbia and Oxford Universities. He was one of the founders of the *Psychological Review*, and of the American Psychological Association, of which he was twice president.

A gifted and prolific writer in the fields of psychology, philosophy, and education, he frequently contributed to periodicals and published half a score of books. Among these are: *The Varieties of Religious Experience*, *The Will to Believe*, *Pragmatism*, *A Pluralistic Universe*, and *The Nature of Truth*. His greatest and most influential work, *The Principles of Psychology*, appeared in 1890, and soon became a classic in an unusually literal sense of the word. With the repeated reprintings, and the translations of several of his books into foreign languages, as French, German, Italian, Japanese, Spanish, or Russian, and the extension of his fame, he was signally honored with degrees by seven foreign and American universities, and with membership in the national academies of science in America, Denmark, England, Germany, Italy, and Russia. As a personality, his was a gentle and universal character, marked no less by its modesty and simplicity.

The chief work of James consisted in a reconstruction of psychology by resetting its problems and by exploring old as well as new fields in search of data for their solution. By his rare mastery of English and his keen sense of the concrete in experience he turned the abstract difficulties in the human subjects into vital interests for the public as well as for students in general. He elaborated no closed system of psychology, and organized no school of psychologists. Working with the new and strong tide of the theory of evolution, he respected past achievements as well, bringing together and rendering mutually helpful varied materials from the associational, experimental, pathological, and physiological developments in the science. His characteristic contributions consisted in showing consciousness to be a process, this use of the cerebralistic hypothesis, his explanation of habit, his appeal to instinct, a new theory of emotion (shared with Lange), and the typical analysis of special processes, such as the feeling of relation, self, reasoning, and will.

In his philosophy James made his approach to problems through his psychology, the former being in many respects a direct application of the latter. His devotion to truth in all its apparent forms and his abhorrence of the abstractions of the past led him into anti-intellectualism and empiricism. He stimulated new interest in speculation in terms of behavior and expediency, and actively fostered current pragmatism. "We are acquainted with a thing as soon as we have learned how to behave toward it." His philosophical efforts centered on the nature of man's mind, the knowledge which it fashions, and the basis of religious ex-

perience, and encouraged an optimistic attitude toward the experience and the world which man is creating.

Educational theory and practice, particularly in America, are greatly indebted to James. The rising Herbartian movement was met by his contributions derived from a more enlivening, yet less systematic, psychology. What is being done with children in schools to-day, by way of letting the order of subjects and the methods of teaching follow the lead of the native activities and interests, is in part an outcome of his influence. His conception of education and his views of the work of the teacher appeared in the widely read *Talks to Teachers on Psychology and to Students on Life's Ideals*. "Education is the organization of acquired habits of conduct and tendencies to behavior." "The great thing in all education is to make the nervous system our ally instead of our enemy." "No amount of culture would seem capable of modifying a man's general retentiveness." By directing attention to the value of instincts as the equipment for education, by emphasizing the importance of the formation of habits, and by the serious doubt he threw around the doctrine of formal discipline, he fostered a descriptive study of the data of teaching and hastened the coming of experimental pedagogy. **JAMES MILLIKIN UNIVERSITY, DECATUR, ILL.** — Founded in 1901 by the amalgamation of Lincoln College, Lincoln, and the Decatur College and Industrial School. The institution which is coeducational is under the supervision of the Synods of Indiana, Illinois, and Iowa of the Presbyterian Church. The University includes a preparatory school and the college, which gives courses in liberal arts, engineering, fine arts, domestic economy, music, commerce and finance, pedagogy, and library science. The entrance requirements are fifteen units. The degrees of A B and B S are conferred. The faculty consists of sixty-four members.

**JAMESTOWN COLLEGE, JAMESTOWN, NORTH DAKOTA.** — A coeducational institution which was organized in 1883, and gave instruction until the spring of 1893, when instruction was suspended. In 1909 the college was reopened with an enrollment of 102 students.

The enrollment in 1912 was 190. The college is under the auspices of the Presbyterian Church. The plant consists of five buildings, and a campus of 107 acres. There is a permanent endowment of \$200,000. It is the only college now operating in the state west of Fargo and Grand Forks, a territory of 140,000 square miles. Courses are offered leading to the degrees of A. B. and B. S., courses in music, in expression, in domestic science, in commercial subjects, and in secondary subjects, as well as regular college courses. Fifteen units in high school are required to enter the college. There is a faculty of sixteen members.

**JANITOR, SCHOOL** -- An official who takes care of a school building, e. g. sweeps and cleans it, looks after the heating of the building, makes minor repairs, and renders such miscellaneous service to the principal and teachers as may be required. The position is one of importance, and it is capable of becoming much more so than it is as yet, except in a few favored places. Too often the position of janitor in our city schools is filled by rewarding political service, and not infrequently a relatively poor janitor is safe from dismissal, because he is supported by those whom the superintendent of schools does not think it wise to antagonize. It not infrequently happens, too, as a result of this political basis of selection, that the janitor of a school building receives a larger yearly salary than the teachers who teach in it. With some form of civil service tests, and with appointment and dismissal by the business manager for the Board of Education instead of by the Board itself, the position can be made one of much importance in the management of a school system.

#### JAPAN, EDUCATION IN. -- Historical --

The present educational system of Japan dates from 1872, when the first education code under the new régime was published. In 1868 took place the great event called *The Restoration of Meiji*, Meiji being the name of the new era then inaugurated. Up to that time, for some seven hundred years, the whole administrative power of the empire had been in the hands of the military class, the head of which under the title of *Sei-I-Tai-Shôgun* (*generalissimo for subjugation of barbarians*) was *de facto* ruler of the country, under him, there were military lords, each having an almost autonomous power in his own territory. In 1868 the *Shôgun* gave up his power into the hands of the Emperor, and in 1871, the feudal system was finally abolished. The military class lost its monopoly of civil and military services and all classes were made equal before the law. The first education code of 1872 established equality of all classes in educational matters and the principle of compulsory education. The preamble to the code says: "It is intended that henceforth universally without any distinction of class or sex, in a village there shall be no house without learning (education), and in a house no individual without learning. Fathers and elder brothers must take note of this intention, and, bringing up their children or younger brothers (or sisters) with warm feeling of love, must not fail to let them acquire learning. As for higher learning, that depends upon the capacity of individuals, but it shall be regarded as a neglect of duty on the part of fathers or elder brothers, should they fail to send young children to primary schools at least without distinction of sex." But before entering upon the description of the present system initiated by the new code, it will not be without interest to touch briefly upon the education in the old feudal days before the new era, for it was chiefly men educated under the old régime, who have been leaders in the evolution of modern Japan.

With the introduction of the Chinese civilization in the seventh and eighth centuries, learning began to be cultivated, and in accordance with provisions of the education section of the famous *Taihô* code issued in 701 A.D. a university was established in the capital for study of classics (or philosophy and history), law, literature, music, calligraphy, and mathematics, all except law being exclusively Chinese; a school was also established in every province: only the children of higher officials were, however, admitted either into the university or to

provincial schools. With the rise of the military class and the establishment of feudalism, those fell into decay, and for centuries the only places where people could obtain any teaching were Buddhist temples, even sons of great military chiefs receiving their education there, if at all. It was only towards the end of the seventeenth century, when the country began to enjoy continued order and tranquillity under the Shōgunate of the Tokugawa family, that any regular provisions were made for education. Even then it was chiefly confined to sons of *samurai* or military men, and it was not till some hundred years later that schools began to be established in any number for common people. In fact, higher learning was limited to the *samurai* class, while of the others, including farmers, artisans, and merchants (to name them in the order of the social scale of the time), the large mass was entirely without any education or with only the elements of reading, writing, and arithmetic; while the number of those who acquired any literary culture was small indeed. The education of *samurai* in those days consisted in the study of Chinese classics and of training in military arts, they were taught in schools established by each feudal lord for his retainers, while those who showed any special ability, either in literary studies or military arts, were allowed or sometimes ordered to proceed to study further with noted masters throughout the country. There was an academy in Vedo (now Tokyo), the seat of the Shōgun's government, where noted professors gave lectures on Chinese classics, there were also private academies kept by masters, to which scholars flocked, attracted by their fame. Other studies were also cultivated to a certain extent such as Japanese literature (in contradistinction to the Chinese), mathematics, medicine, etc., and, notably towards the latter part of this period, the Occidental learning through the study of the Dutch language. It is a mistake to suppose that we began to study Western arts and sciences only within the last fifty years, — after the coming of Commodore Perry, there were earnest students, though few, who under great difficulties read such foreign books as were brought into Japan by the Dutch and in several cases translated them into Japanese or sometimes Chinese, which was the language of the learned at the time.

Under the new régime, which began in 1868, education was encouraged from the very beginning. The academy of foreign languages, which had been in existence before, was reopened and enlarged, developing in the course of some ten years into the University of Tokyo, while many new schools were opened. Students were sent abroad; foreign teachers were engaged, among others being an American normal school teacher, who was placed in charge of the newly opened normal school and taught the method of class teaching in primary schools; under his direction were

compiled schoolbooks and wall charts entirely after the American model. This school was opened in June, 1872, and in September of the same year the new education code was promulgated, which introduced an entirely new system of education after the Occidental model. The provisions of the new code were too ambitious to be carried out completely at the time. Moreover, they had been copied too closely after a foreign model and some of them were found to be unsuitable for the country. During the forty years which have elapsed since that time, many and great changes have been made; but the fundamental principle enunciated, that everybody without distinction of class or sex shall receive primary education at least and that equal opportunities shall be given to all to receive higher education according to their ability, has always been maintained.

**Present System — General Outline** — Education is regarded as one of the most important functions of the state and is placed entirely under the state control, there is a Minister of Education who is a member of the cabinet and is in charge of all administrative matters connected with education. It is to be observed that the educational system of Japan is not determined by laws which have to pass through the two houses of the Imperial Diet and to be sanctioned by the Emperor, but more important matters connected with the educational system are regulated by imperial ordinances, which are issued by the Emperor on the recommendation of the cabinet after being submitted to the Privy Council. These are also submitted by the minister previous to their proposal by him in the cabinet to the High Educational Council, an advisory body composed of presidents of imperial universities, of heads of different colleges and schools, of certain coopted members, of members representing the Departments of the Interior, of Agriculture and Commerce, of Army, and of Navy, and of members specially appointed for their educational experience and knowledge. There are imperial ordinances relating to primary (or elementary) schools, middle schools, girls' high schools, normal schools, higher schools, special colleges, technical schools, imperial universities, private schools, etc.

**General** — Let us begin with a brief outline of the whole educational system as determined by those ordinances. At the base of the whole system is the primary school. Below this, there is the kindergarten, which, however, can scarcely be said to form a part of the national educational system. The primary course is divided into ordinary and higher. The ordinary primary course extends over six years and is compulsory for all children who have completed their sixth year. After finishing the ordinary primary course, a child may go on to the higher primary school with a course extending over two or three years. Supplementary courses may be provided for

children who at any stage after the completion of six years' compulsory education cannot proceed further with regular education. In primary schools, boys and girls are usually taught together in the same schools and often in the same classes, especially in the ordinary primary, there being but little difference either in the matter or manner of teaching. But beyond the primary, the education of boys and girls becomes distinct both as regards schools and subjects. After six years of the ordinary primary course, a boy who proposes to pursue higher education will, instead of going on to the higher primary, enter a middle school. A middle school has a course of five years to which may be appended a supplementary course of one year. After passing through the middle school, a boy intending to pursue the university course enters a higher school, having a course or rather courses of three years, preparatory to different colleges or faculties of the imperial universities. This would correspond approximately to the first two years of the college course of American universities. After finishing three years of the higher school course when he is between twenty and twenty-one years of age, supposing him to have passed through all the stages without any interruption, he enters one of the colleges or faculties of the imperial universities, having an undergraduate course of three or four years, after which he may pursue further study as a postgraduate student. Instead, however, of proceeding to the imperial universities, a boy may, after he has finished the middle school, enter at once a special college or a technical special college. This college must be distinguished from the college of an imperial university and is more like an American college in its standard and scope.

It should be mentioned that in all cases the graduation from one school or college is a qualification for entrance into the next higher stage, but in recent years the demand for higher education has increased at such a rate that, notwithstanding the very great and rapid expansion of educational resources (see tables at the end), at almost every stage a competitive examination has to be held for admission, the number of candidates for admission being from twice, thrice, to even in some cases as large as ten times the number of those that can be admitted. After leaving a middle school, a boy may also enter a higher normal school for the training of secondary school teachers, or one of the military and naval schools or the navigation school for training of officers of the merchant marine, etc. After two years of higher primary school (or after two years of middle school) a boy may enter a technical school, *i.e.* a school for the teaching of industrial arts (manufactures, engineering, technical arts), agriculture, commerce, navigation, etc. The length of a course in these schools is generally three years, so that a boy will finish his

education on this line at about the same age as the boy who has taken a middle school course will have finished his. There are technical schools of even lower grade than this, to which boys are admitted after finishing the ordinary primary school. There are also technical supplementary schools for those who have finished the ordinary or higher primary course.

A girl's education runs on a similar line as far as it goes. Thus after finishing the ordinary primary school, instead of going on to the higher primary, she may enter a girls' high school. The usual length of the course in a girls' high school is four years but may be five years; a supplementary course of two years may be added. In the girls' high school attached to the female higher normal school in Tokyo, the course is five years, with a supplementary "special" course of three years. There is no provision made either by the central or local government for girls desiring to receive a higher education than the supplementary courses of girls' high schools, except female higher normal schools for the training of female secondary school-teachers; but several colleges have been established by private individuals. Besides high schools, there are also technical schools of various grades, just as for boys.

Normal schools for the training of both male and female teachers of primary schools form a separate class by themselves. Their graduates are eligible for admission into the higher normal schools already mentioned equally with the graduates of middle schools and girls' high schools.

There are thus several grades of schools and colleges; first, primary schools with kindergartens and some other schools of the same grade, including some technical schools; next, secondary schools, including middle schools, girls' high schools, technical schools, and normal schools; above them are special colleges for law, medicine, science, literature, fine arts, etc., and technical special colleges for technology, engineering, agriculture and forestry, commerce, etc., besides higher normal schools and higher schools preparatory to the imperial universities; and lastly come the imperial universities with their colleges of law, medicine, science, literature, engineering, and agriculture.

**Moral Instruction** — The object of the primary education is defined in the first article of the Imperial Ordinance on Primary Schools as follows: "Primary schools are designed to give children the rudiments of moral education and of civic education, together with such general knowledge and skill as are necessary for life, while due attention is paid to their bodily development." From which it will be seen that great stress is laid on moral instruction; and this is the case, not only in primary schools, but in schools and colleges of all grades and kinds. It is a national tradition that the primary object of education is moral training.

University of Tokyo

Handwork

Class Room Recitation

Gymnastics.

Training in Etiquette (Tea Ceremony.)

Thus in the old feudal days Chinese classics and philosophy were studied by young *samurai*, not so much for literary purposes as for moral training and intellectual culture. They were thereby taught their responsibility as members of the ruling class, and how to discharge this responsibility; there they read of deeds of great and wise men; by such means, through precepts and examples, a spirit of loyalty to their lords and filial piety to their parents, of reverence for the Imperial House and veneration for their ancestors was inculcated. For the lower classes of people conditions were similar, only in a lesser degree, textbooks for popular instruction in reading and writing were chiefly moral lessons. Thus, there was no necessity for special moral instruction in those days; but under the new system with the introduction of so many different subjects, it was found necessary to devote a certain number of hours specially to moral instruction. But here arose a difficulty as to what should be made the basis of the moral teaching. It seemed impossible to return to the old Chinese philosophical teaching, Buddhism (*q'u*) had been discarded as the national religion, some, while not themselves believing in Christianity, nevertheless thought it might be adopted as the basis of our ethical teaching, there was even some wild talk of a new religion, we seemed to have cut loose from our old moorings and to be drifting, no one could say whither. People seemed to have forgotten that in our old tradition of devotion to the Imperial House and reverence for ancestors, of loyalty and filial piety, we had a most valuable inheritance which has always explicitly or implicitly formed the basis of our moral teaching, even in the days of ascendancy of the Chinese influence. But this was now formulated in the memorable Imperial Rescript issued in 1890 by the Emperor. It runs as follows —

#### IMPERIAL RESCRIPT ON EDUCATION

Know ye, Our subjects

Our Imperial Ancestors have founded Our Empire on a basis broad and everlasting, and have deeply and firmly implanted virtue. Our subjects ever united in loyalty and filial piety have from generation to generation illustrated the beauty thereof. This is the glory of the fundamental character of Our Empire, and herein also lies the source of Our Education. Ye, Our Subjects, be filial to your parents, affectionate to your brothers and sisters, as husbands and wives be harmonious, as friends true, bear yourselves in modesty and moderation, extend your benevolence to all, pursue learning and cultivate arts, and thereby develop intellectual faculties and perfect moral powers, furthermore, advance public good and promote common interests, always respect the Constitution and observe the laws, should emergency arise, offer yourself courageously to the State, and thus guard and maintain the prosperity of Our Imperial Throne coeval with heaven and earth. So shall ye not only be Our good and faithful subjects, but render illustrious the best traditions of your forefathers.

The Way here set forth is indeed the teaching bequeathed by Our Imperial Ancestors, to be observed alike by Their Descendants and the subjects, infallible for all ages and true in all places. It is Our wish to lay

it to heart in all reverence, in common with you, Our subjects, that we may all attain to the same virtue.

The 30th day of the 10th month of the 23rd year of Meiji (October 30th, 1890)

Imperial Sign Manual. Imperial Seal

Such is the Rescript that now forms the basis of our moral education; it will be observed that the two cardinal virtues are loyalty, which with us is identical with patriotism, and filial piety, meaning thereby, not filial piety to our immediate parents only, but to our ancestors for generations. The precepts given are nothing new but "teaching bequeathed by the Imperial Ancestors," and the Emperor calls upon us to join with him in observing those precepts by appealing to our loyalty and filial piety. The message that the Rescript conveys to us cannot be properly understood without the knowledge of the peculiar relation between the Imperial House and the people, and of the spirit of reverence for ancestors, in fact it may be said that the most important object of our moral education consists in so imbuing our children with the spirit of the Rescript that it forms a part of our national life.

A copy of the Rescript is distributed from the Department of Education to every school in the Empire, those under government control being actually signed by the Emperor. To foster the spirit of loyalty, portraits of the Emperor and the Empress are distributed from the imperial household to every government and public schools above the grade of higher primary inclusive, and to some private schools. These are brought out on all public occasions and school functions, at which also the reading of the Rescript always plays an important part.

Two hours a week are given in primary schools to lessons in morals. The following directions as to these lessons are given in the regulations —

The teaching of morals must be based on the Imperial Rescript on education, and its aim should be to cultivate the moral nature of children and to guide them in practice of virtues.

In the ordinary primary course, easy precepts appropriate for practice concerning such virtues as filial piety and obedience to elders, affection and friendship, frugality and industry, modesty, courage, etc., should be given, and then some of the duties towards the State and society, with a view to elevate their moral character, strengthen their will, increase their spirit of enterprise, make them value public virtues, and foster the spirit of loyalty and patriotism.

In the higher primary course, the above must be further extended and training given made still more solid.

In the teaching of girls, special stress must be laid on the virtues of chastity and modesty.

Encouragement and admonition should be given by means of wise sayings and proverbs and by tales of good deeds, so that children may lay them to heart.

At present textbooks compiled on these lines by a special commission, appointed in the Department of Education for the purpose, are in use in all the schools.

Similarly for moral lessons in middle schools, to which an hour a week must be given, the following directions are given:—

The teaching of morals must be based on the precepts of the Imperial Rescript. Its object is to foster the growth of moral ideas and sentiments, and to give boys the culture and character necessary for men of middle and higher social standing, and to encourage and promote the practice of virtues. The teaching should begin with an explanation of the essential points of morals in connection with daily life by means of good words or maxims and examples of good deeds, to be followed by a little more systematic exposition of the duties to self, to family, to society, and to the State. Elements of Ethics may also be taught.

For girls' high schools, where two hours a week are devoted to moral lessons, almost the same directions are given, but here in addition lessons must be given in manners, under which are included, not only personal conduct, but various social observances. In other schools, at least an hour a week is given to moral lessons, always based on the Imperial Rescript and on similar lines, but adapted to the age and future position and occupation of pupils; thus, for instance, in commercial schools great stress is laid on various phases of commercial morality.

**Physical Education and School Hygiene.** — As seen in the article above quoted, defining the object of the primary education, a great deal of attention is paid to the physical development of children. In the old feudal days, sons of *samurais* spent a large portion of their time in practising military arts, such as fencing, archery, riding, use of spears, *jūjutsu*, etc., which of course was an excellent physical training, as for children of other classes, their plays and games and even work in open air with but little school teaching kept them healthy and strong, while it was deemed unwomanly for girls, especially in the middle and higher classes, to take any kind of active exercises. Hence when the new education was first introduced, no need of physical education as such was considered, and while boys and girls, young men and women were subjected to much harder mental work than before, they had scarcely any physical exercise. The consequences soon made themselves apparent on the physique of educated youths, and weak sight and pale consumptive features came to be regarded as characteristic of students. Such a state of things could not be allowed to go on; a teacher of gymnastics was engaged from America, who trained teachers of gymnastics, and by this means a system of gymnastics after the German model was introduced into all the schools. Various modifications have since been made in the method of teaching very young children in primary schools are now taught plays and games, while older boys in primary and all higher schools practice military gymnastics and drill in addition to common gymnastics. In girls' schools, square dances are taught as exercises, and the Swedish system of gymnastics has been introduced to some extent. Besides systematic teaching in gymnastics, foreign games and sports have been introduced: baseball is now a very popular

game, and there are lawn tennis courts in almost every school, while boating and athletic sports have their votaries. At the same time old military arts have been revived as physical exercise, especially fencing and *jūjutsu*, which in some schools are made almost compulsory, and, in a less degree, archery. Schools of every grade have their annual or semi-annual school excursions (*q.v.*), which, while undertaken primarily for the purpose of instruction in geography, history and science, afford a great deal of training in long-distance walking and marching, hill climbing, etc.

Medical examination of school children is made by medical officers in April of every year under the following heads. (1) height, (2) weight, (3) circumference round the chest, (4) the spine (scoliosis and kyphosis, *q.v.*), (5) general constitution, whether strong, medium, or weak, (6) eyesight; (7) diseases of the eye, (8) hearing, (9) diseases of the ear, (10) teeth, (11) diseases in general, especially scrofula, insufficient nourishment, anæmia, *kakke* or *beri-beri*, consumption, megrim, epistaxis, neurasthenia, and chronic diseases. The results of the examination of over one million school children are sent to the Department of Education, where they are collated and examined. It is too early to draw any definite conclusions from these statistics, but there seems to be no doubt that there has been a very remarkable improvement in the physique of our young men and women.

**Primary Schools** — Parents and guardians are under obligation to send children to school, from the beginning of the first school year (April 1) after they have completed their sixth year until they have finished the ordinary primary course, unless they are specially exempted by the mayor or headman of the district on account of mental or bodily infirmities or extreme poverty or for some other valid reason. Hence, an obligation is also laid on the community to establish and maintain a sufficient number of primary schools to accommodate children within its jurisdiction, tuition being, of course, free, the community may be a city, a town, a village, or a union or a division of the same, as the case may be. Special permission must be obtained from the mayor or headman to pursue education at home or at any other school than that established by the community, as a matter of fact, this happens very seldom except in Tokyo, so that practically all children in Japan receive their primary education in common schools without any social distinction. In Tokyo the upper classes are beginning to complain that by sending their children to the same schools as those of the lower classes they suffer in their manners and speech, and also in their intellectual progress, and a few private schools for children of the rich have been started within recent years.

**Curriculum.** — The subjects taught in primary schools are, besides morals and gymnastics al-

ready mentioned, language (reading, writing, and composition), arithmetic, geography, and Japanese history, science (or nature study), drawing, singing, sewing (for girls only), and manual work, making all together from twenty-one to thirty hours a week. It should, however, be mentioned that an hour means usually a forty-five minutes' lesson (or even less), followed by fifteen minutes' play. In higher primary schools the subjects are mostly a continuation of the same, except that elements of agriculture or commercial knowledge and the English language are usually added. As to language, Japanese children are very much handicapped by the fact that they have to learn a large number, some 1500, of Chinese characters in common use in Japan. In arithmetic, almost all our weights and measures being in decimal system, it is not necessary to introduce fractions very early, in fact not until the last, or sixth year, of the ordinary primary. Sewing forms a very important subject for girls, not only in primary schools, but throughout their school course.

**Teachers** — Primary school teachers must have certificates or licenses, which are granted to graduates of normal schools and of certain other prescribed schools and to those who have passed the examination held annually in each prefecture, the standard of which is the same as for graduation from normal schools. The normal schools are maintained by the prefectures for the training of primary school teachers and have a four years' course, and, in some cases, a preparatory course of one year. The qualifications for entrance into the preparatory course are that candidates shall be of good moral character and sound constitution and shall have finished two years of the higher primary course. The last, or fourth year, of the normal school course is largely devoted to practice in teaching in the primary school attached to every normal school. A graduate of a middle school or a girls' high school may enter a normal school for one year, during which he or she studies the theory and practice of pedagogy, and becomes qualified as a primary school teacher. It will be seen from the above that the qualifications for primary school teachers are not very high; yet so great has been the educational expansion that the supply of teachers has not kept pace with the demand, and many not properly qualified teachers have to be employed. It may be remarked that this is the case not only in primary education, but in every grade and kind of education in Japan. The salaries of teachers, from university professors to primary school teachers, are very inadequate; this, no doubt, is one of the reasons why the supply of teachers is not sufficient to meet the demand. More than half of the primary school teachers have salaries ranging between 15 and 24 yen (\$7.50 to \$12) a month, which, even allowing for the low rate of living in Japan, is very inadequate; the highest salary for a university professor is about 4000 yen

(\$2000). All teachers in government or public schools and colleges are entitled to a pension equal to one fourth the amount of their salary at the time of retirement, if they retire after fifteen years of service, and to "additional  $\frac{1}{10}$ th the amount of their salary for every year exceeding fifteen."

**Middle and Higher Schools.** — *Curriculum* — The subjects taught in middle schools are morals, the (Japanese) language, and Chinese literature, a foreign language (one of the three, English, French, and German), history, geography, mathematics, natural sciences, physics and chemistry, law and economics, drawing, singing, and gymnastics, of which law and economics and singing may be omitted. None of those call for special remark, except "the language and Chinese literature." One who is not acquainted with our language may well wonder why Japanese language and Chinese literature should be coupled as one subject in this way, but the fact is that with the introduction of Chinese civilization we not only adopted Chinese literature almost as our own and introduced very many Chinese words into our own language, but even adopted Chinese characters into our writing, so that at present ordinary Japanese literature is written or printed with Chinese characters, amongst which our own are interspersed. It would take too long to explain this anomalous state so as to be intelligible to a foreign public, but it is a very great handicap indeed, not only for our boys and girls, who have to learn three or four thousand Chinese characters, but also for the general public, for it prevents the use of typewriters, linotypes, and similar instruments based on the use of a limited number of characters.

**Teachers** — Teachers in secondary schools are required to have a certificate, granted by the Department of Education to the graduates of higher normal schools and of certain other institutions, as for instance colleges of science and of literature of the Imperial universities, and to those who have passed examinations held annually by the department for the purpose. As already stated, however, a large number of teachers without certificates have to be employed for want of certificated teachers. The tables appended below will show that there has been a steady improvement in this respect.

**Higher Schools** — The question of secondary schools is a very difficult problem in every country, even in Germany, which may be said to be a leading authority in every educational question, this problem seems to be still a matter of discussion. In Japan the problem presents serious difficulties. The present middle school course is not sufficient as a preparation for Imperial universities, not only because the standard in the universities is high, but also because to pursue higher studies of this standard in Japan at present requires a knowledge of two or at least one of the occidental languages, so

entirely different in their structure and nature from the Japanese language, and presenting corresponding difficulties to Japanese students, far greater than French or German to an American. This chasm between middle schools and universities is bridged over at present by "higher" schools, having three different courses of three years preparatory to different colleges of the universities. Thus the normal age of a student when he is ready to enter an Imperial university is above twenty, it will be seen that the higher school courses correspond both in their standard and the normal age of students somewhat to the first two years of the college course of American universities. There are at present eight higher schools, capable of admitting about 2000 new pupils annually, and as there are between 7000 and 8000 applicants for admission (graduates of middle schools and thereby duly qualified), higher schools and consequently universities obtain a number of tolerably select students. At the same time, however, the voice of discontent of the nonadmitted is loud, and, indeed, it is a great problem what to do with them, many of them enter private, so-called universities, of which mention will be made later.

At a session of the High Educational Council, held in the spring of 1910, it was decided that higher schools should be replaced by higher middle schools having two courses of two years and a term, not simply preparatory to the universities, but giving a higher general liberal education, one of the courses being literary and the other scientific, it is thought that the graduates will be qualified to enter Imperial universities at the same time that they receive general liberal culture. Permission will be given to prefectures and private individuals to open higher middle schools, and several will no doubt be established within a few years, so that the present state of congestion at the entrance of higher schools will be avoided. This decision in a modified form was approved by the late minister of education; the only question is whether in two years and a term, instead of three years, as heretofore, students will be so prepared as to satisfy university authorities.

**Imperial Universities** — These institutions are established and maintained by the central government. There are at present four, one in Tokyo (f. 1868) and one in Kyoto (f. 1897), one in the Northwest and one in Kyūshū in course of organization. Each university consists of several colleges or faculties, six in Tokyo, viz. colleges of law, medicine, engineering, literature, science, and agriculture, and four in Kyoto, viz. colleges of law, medicine, literature, and science and engineering; the Northwestern University has at present colleges of science and of agriculture; and the Kyūshū University those of medicine and engineering. Those colleges are like professional schools of American universities, except those of science and literature,

which would correspond approximately to the last two years of the American college course and a little more. In each college, there are prescribed courses, which may be taken up by students in Tokyo, in the college of law, there are courses of four years in law proper, politics, political economy, and commerce; in the college of medicine, besides a course of four years in medicine, there is a course of three years in pharmacy; in the college of engineering, there are courses of three years in civil engineering, mechanical engineering, naval architecture, technology of arms, electrical engineering, architecture, applied chemistry, technology of explosives, mining, and metallurgy, in the college of literature, courses of three years in philosophy, history, and literature, each of them being subdivided into several branches, such for instance as Japanese, Chinese, English, French, and German literatures at the last, in the college of science, courses of three years in mathematics, astronomy, theoretical and experimental physics, chemistry, zoology, botany, geology, and mineralogy; in the college of agriculture, courses also of three years in agriculture, agricultural chemistry, forestry, and veterinary medicine. In Kyoto there are similar courses. A hospital is attached to the college of medicine for the purpose of clinical instruction. After graduation, students may remain in the university as postgraduate students. Tuition fees, inclusive of everything, amount to 50 yen (\$25). The enrollment at Tokyo in 1909-1910 was 5649, at Kyoto 1424.

**Special Colleges.** — Under the nomenclature of special colleges are classed institutions for the instruction of special subjects, other than the Imperial universities, whose entrance qualification is graduation from middle schools or girls' high schools, or higher. There are special colleges for law, medicine, literature, languages, sciences, arts, music, etc. There are five colleges of medicine maintained by the central government and several established by the local government or private individuals; these medical colleges all have a course of four years, but their standard is necessarily lower than that of the Imperial universities, students not being so well prepared, especially in foreign languages. Many of the private institutions teaching law, literature, and theology (Buddhist or Christian), and styling themselves universities, are officially classed under this head, among these, the most noted are the Kei-O-Gijuku founded by the famous educationalist Fukuzawa, and Waseda Daigaku founded by Count Okuma, with faculties of law and literature, and the Joshi Daigaku (Women's University). Some of them have a large number of students, but most of them are suffering from want of funds; for, with very few exceptions, they have scarcely any endowment, nor can they charge high tuition fees. Among other special colleges may be mentioned Foreign Languages School, Academy of Fine Arts, and Academy of

Music, all in Tokyo and maintained by the central government. There are, besides those, technical special colleges, of which, however, I shall speak under the next head. The College of Navigation, for the training of officers of merchant marine under the Department of Communications, and the College of Fisheries and Marine Products, under the Department of Agriculture and Commerce, also fall under this category.

**Technical Schools** — A great deal of attention has been paid to technical education, more especially within the last fifteen years, and a large number of new technical schools has been recently brought into existence, and old ones have been enlarged both in scope and accommodation. By technical education is meant education in engineering and technology, industrial arts; agriculture in all its branches, including sericulture and veterinary medicine, forestry, fisheries and marine products, navigation, and commerce. There are several grades of schools, leaving out the engineering and agricultural colleges of the Imperial universities, there are immediately below them technical special colleges, admitting graduates of middle schools and having a course of three or four years, below these are technical schools of two classes, *A* and *B*. Schools of class *A* are of about the same standing as middle schools, admitting boys or girls who have finished two years of the higher primary, or under certain conditions two years of a middle school or a girls' high school, they have generally a course of three years, sometimes four, and their graduates are under certain conditions admitted to technical special colleges. Schools of class *B* admit boys or girls who have finished the ordinary primary, and usually have a course of three years. In addition to these there are technical supplementary schools for giving general and elementary technical knowledge to those who cannot enter regular schools, they are mostly night schools.

Technical special colleges are mostly government institutions, among which are the engineering or technological colleges of Tokyo, Osaka, Kyoto, Nagoya, Kumamoto, Sendai, Yamagata and Akita, the commercial colleges of Tokyo, Kobe, and Yamaguchi, Nagasaki and Otaru, and the agricultural college of Morioka. There are several institutions attached to these, to train teachers for technical schools of class *A*, want of good teachers being a great hindrance to their establishment, which is greatly encouraged by the government. A sum of 350,000 yen (\$175,000) was voted by the Diet as subsidy for the encouragement of technical education for the year 1908, this sum being distributed to the schools and colleges established by the local governments.

**Female Education.** — In the old feudal days a girl's education generally stopped at an elementary stage, even for daughters of *samu-*

*rai*. They were taught to read and write, and to sew, while those of richer classes were also taught many accomplishments, such as music and dancing, *chanoyu* (tea ceremony), flower arrangement, etc. There were some, especially among the *samurai* class, who received much higher literary culture, but they were only a small minority. Under the new régime, female education received great encouragement. The preamble to the first education code already quoted is emphatic on the point that no distinction shall be made as to sex at least in primary education. A girls' school was opened in 1871 with an American teacher to teach English, in the following year a female normal school was opened by the Empress herself, an event without precedent in the history of Japan. But notwithstanding the encouragement given to the female education by the government, it is only quite recently that people in general have begun to recognize its importance. In 1873, a year after the promulgation of the code, out of a total of 1,145,800 attending primary schools, 77 per cent were boys and only 23 per cent girls, in 1883 the total had increased to 3,238,000, but the ratio of boys to girls was 68 to 32, statistics for 1893 show no great advance either in the total number (3,338,000) or in the ratio of boys to girls (66 to 34), but in 1908 the total had increased to 5,996,000, showing an enormous stride made in primary education since the China War of 1893-1894, and the ratio of boys to girls shows the same satisfactory progress, being 57 to 43. In secondary education, the same thing is to be observed, in 1883 there were only 7 girls' high schools with 350 pupils, besides a few schools of about the same standing but not quite satisfying the requirements of a high school, in 1893 the number had increased to 28 with 3020 pupils. The official report for 1908 gives 159 schools with 46,580 pupils, and the number seems to be increasing at the rate of more than 20 a year.

The course in a girls' high school is mostly four years, the subjects taught are morals, the (Japanese) language, a foreign language, history, geography, mathematics, science, drawing, household matters, sewing, music, and gymnastics. The standard is not quite as high as in middle schools. The foreign language may be either French or English, actually there is no school, except the "Peacocks School," where French is taught. A general supplementary course of two or three years may be added for those who, having finished the regular course, desire to receive a further education, these correspond somewhat to the college courses, but they are not very largely attended, girls staying at home to learn sewing and housekeeping with their mothers, or receiving private lessons in music, *chanoyu*, and other accomplishments.

A girl who has finished the girls' high school

## JAPAN

may enter a female normal school for two years and become qualified as a primary teacher, or she may enter one of the two higher female normal schools and pass a four years' course, when she becomes qualified as a secondary teacher. There are also a few private colleges where girls may receive education in literature, languages, etc. There is at present no means by which a girl may enter one of the Imperial universities. There are also technical schools for girls of different grades as for boys, although not so many; subjects taught in them are sewing, household matters, embroidery, artificial flower making, sericulture, filature, etc.

**Statistics** — The statistics which are appended here to give some idea of the extent and progress of education in Japan are compiled from materials given in the Reports of the Department of Education, mostly from that for the year 1908–1909.

### GENERAL VIEW OF SCHOOLS AND COLLEGES

N B Slight discrepancies in the above tables are due to various facts, as, for example, in one table a branch school is counted independently and in the other not, and so on, they are not such as are significant D K

**Korea, Education in.** — Korea (Morning Splendor), since 1910 part of the Empire of Japan, is a peninsula covering with its archipelago 85,000 square miles, with a population of 12,934,282, in 11 provinces, 317 districts and 4362 villages. Roughly speaking, it consists of an eastern mountain ridge fronting precipitously the nearly tideless sea of Japan, and a long western slope which faces China and a sea containing many islands and with tides rising over thirty feet. Thus, in history and geography, Korea has had her back to Japan and her face to China, the former being in her traditions the land of savages and pirates, the latter the sun and sum of all power and culture. In popular legend the founder of Korean civilization is Kija (Ki-tsze), ancestor of Confucius, who in 1122 B.C., with five thousand followers settled east of the Yalu river. Critical scholarship, however, knows nothing of Kija's presence within the limits of modern Korea. As with the Japanese, the Korean historiographers, when, nearly two thousand years later, first practicing their art, followed in imitation and rivalry their only model, the Chinese, carrying back antiquity as far as possible and ascribing their national beginnings to a great name and looming personality. The foundations of all early Korean historiography,

like the Japanese, lie in the annals of China, whence writing was derived. Among the tribes of the peninsula, three states (A.D. 9-960) arose, in the north, east, and west, into which Chinese letters and culture filtered, but it was the entrance of Buddhism, 384 A.D., which, destined to a thousand years of activity, opened the literary, artistic, educational, and intellectual history of Korea. The state predominant in the Middle Ages was Silla (Shinra), whence students traveled to China in ships guided by the mariner's compass, and returning greatly extended the knowledge of Chinese ethics, letters, and philosophy. From A.D. 960 to 1392, under the name of Korai (whence Korea), the peninsular peoples were united and became for the first time a nation, uniform in language, law, religion, and social customs. After several centuries of clash and rivalry between the two systems, Confucianism won the day over Buddhism, at the fall of the old Korai dynasty and the establishment of that ruling from 1392 to 1910, since which time the Chinese system has been the monopoly of the privileged classes, scholars, and office holders. Korean Buddhism, exiled, in its outward manifestations at least, to the mountain monasteries, and held to mainly by the women of the common people, had not those doctrinal developments so noteworthy in Japan. The basis of all education was the Chinese classics.

The method was for the schoolmaster to have, squatting before him, a dozen or more boy pupils, who first committed to memory, through the eye and ear -- usually bawling out the sounds at the top of their voices -- the characters in order of their composition in the text, and then to "back the book" and recite. Then, by analysis and syntax, reading was made thorough. After that came comment and explanation. The brush-pen was in constant use for both ordinary and rapid writing, and calligraphy was greatly prized. Except some slight knowledge of (Chinese) history and arithmetic, this curriculum comprised the average educated man's training, though a minority went on farther, in reading and mastery of the world of Chinese lore -- poetry, philosophy, commentary, and discussion, -- or excelled in mastery of the brush-pen in calligraphy. Thousands of Koreans can write and decipher numerous ideographs, who cannot read books. In the native newspapers of to-day, read by many of the common people and women, the Chinese logograms are plentifully used, but require no knowledge of Chinese syntax. the mixed script, native and Chinese, being read in the same way as we read our Arabic numerals, terms in Latin letters, and words of Greek origin, as familiar parts of speech. Korea's greatest scholar, Chul-chong in the Silla era, or eighth century, invented or adapted from selected Chinese characters the Nido, or syllabary, which admirably expresses vernacular sounds. Later on, a true phonetic

alphabet, based on the organs of speech and one of the finest of the world, of eleven vowels and fourteen consonants, made of straight lines and circles, called En-mun, was invented by a Korean statesman. The two systems exist side by side. The letters, being associated in all their possible combinations into syllables, 199 in all, are learned, without analysis or separation, by children by rote. In this popular script personal letters are written, and the novels read by women and young people are printed. Being so very easy to learn, and because made the vehicle of the vulgar fiction, the En-mun was despised by scholars. For centuries it lay virtually unused by the learned, until the advent of the missionaries, who to their delight found ready to hand the apparatus of education and evangelism, of which they at once made liberal use. Three or four styles of language still prevail, as in Japan. (1) pure Chinese, (2) Chinese vocabulary set in native syntax, (3) popular book style, vernacular but refined, (4) epistolary style.

The end and aim of all formal education in old Korea was political office. Society had but two classes, the yang-ban (civil and military), office seekers and holders, and the masses or commoners, given up to ignorance and superstition, there being virtually no middle class. The whole outlook on the universe and the world of aims and ideas were changed with the coming of the missionaries in 1885, the first being Horace N. Allen, who, in 1885, founded a hospital under royal patronage. He was soon followed by other physicians, and the natives were given valuable training in the laws of cause and effect. The first teacher and educator was Henry G. Appenzeller, who in 1885 opened a school and began the teaching of the English language and sciences. His school in 1886 was noticed by the king himself, who gave it the name of Hall for the Rearing of Useful Men. About the same time Mrs. W. B. Seranton opened a school for Korean girls, both being soon housed in brick buildings. A government medical school was started by Dr. Horace G. Underwood, Dr. J. W. Heron, and Dr. H. N. Allen, and two American lady physicians served the Queen. Three American teachers, requested by the Korean government, Messrs. Gilmore, Bunker, and Hulbert, arrived in July, 1886, and opened an English language school. From this time forward the native language was seriously studied by foreign scholars, and many writers visited the country and by their writings made Korea better known. Schools for the study of German and French, and other English language schools were established by Europeans. The results of the Chino-Japanese war of 1904-1905 completely altered the intellectual attitude of the Koreans toward China, and they turned to the missionaries for light. As early as 1906, under the energetic administration of Prince Ito, the Japanese themselves, having had already over a generation

of experience, established modern common schools and reorganized the normal, high, and foreign language schools in Seoul. So far the system is a model, rather than an advanced development. As a rule, the number of native teachers compared with Japanese is as two to one. To encourage female education, a girls' high school was established in 1908 to serve as a model, while girls in separate classes were admitted to the public schools. In 1909 the regulations for establishing industrial schools and increasing the curriculum of agriculture, commerce, and industry in the higher schools already in operation, were issued. In December, 1909, 512 Korean, 163 Japanese, and four foreign teachers (679) were serving in 134 schools maintained or appointed by the government, in which were 811 female and 15,445 male students, the usual number in a class being sixty. Only the limitations of finance and the lack of skilled teachers prevent rapid growth. In new places the school established is meant to serve as a model, \$82,700 for all schools were estimated in the budget for 1909. In the normal schools manual training was made compulsory, the classes to number fifty each. Increase of public interest is shown in the 2250 applications made to enter the Seoul Normal School, 194 passing the examination successfully, the number of students in 1908 being 140, and 212 in 1909. For high schools the regulations of 1909 shorten the period of study from four to three years, according to local conditions. The number of applicants far exceeds those who pass the entrance examinations. In 1909 25 teachers taught 269 students, and there were 35 graduates. In the girls' high school, in which 7 teachers taught 151 girls, sewing is compulsory and artificial flower making, optional. In the foreign language school in December, 1909, Japanese, English, French, German, and Chinese were taught. Of 1130 applicants, 307 passed, 38 teachers taught 443 pupils, and the graduates numbered 106. To the old Chinese Classical School modern historical and scientific subjects were added. In the Law School 19 instructors had 138 students under them. In 1909 the seven industrial schools, classified as agricultural, commercial, technical, and supplementary industrial, in which most of the practical branches of learning are taught — the foundries, farms, experimental stations, forestry schools being equipped according to the best science — had 42 teachers and 306 pupils. Of private, which include missionary, schools, by December, 1909, 2180 had received government recognition, and of those duly inspected or instructed, there are two high, two industrial, 1353 miscellaneous, and 829 missionary schools, or 2187 in all. Textbooks must be supervised or approved by the government, and are lent to the pupils, to be gradually paid for. In 1909 202,936 books were sold and 159,314 lent, the number being nearly six times that of 1908. By competitive examination, fifty-two students

were selected and sent to Japan for higher study.

Translation of the Bible into Korean printed with mixed script or En-mun, and its rapid distribution by energetic Bible societies, following upon widespread propaganda and revivals (which have resulted in a total Christian population of 250,000), marked not only with fervor, but with habitual study of the Scriptures, compelled many to learn the alphabet to master a sacred library so rich in substance and novelty, have constituted a national school of intelligence and culture. This is especially noticeable in Seoul and Ping Yang.

In spite of the handicap to education which the hereditary hatred of Koreans to their conquerors, the survival of sedition, the prevalence of early marriages the brides being usually older than the grooms — the age — old prejudice against manual labor by the intellectual classes, education promises to be universally appreciated the Koreans having an innate love of letters and respect for scholarship. W. E. G.

**JEALOUSY** — A complex emotion which always involves some feeling of self-consciousness on the part of the jealous individual. The rights or desires of the jealous individual are in some way felt to be invaded, whereupon the individual is aroused to anger and the tendency to assert his own rights, either real or fancied. McDougall (*Social Psychology*, p. 138) reduces the emotion of jealousy to the fundamental instinct of possession or ownership, and holds that the earlier forms of jealousy which appear in animals and young children are primarily forms of anger or fear. The emotion has also been described by Ribot (*Psychology of Emotions*), who quoted with approval Descartes' definition "Jealousy is a kind of fear related to the desire we have of keeping some possession."

Whatever may be said of the psychological character of this emotion, it is a matter of common experience that it is one of the earliest forms of social experience. Certainly the consciousness which is involved need not be of any very elaborate type. The child becomes aware of his own desires and possessions by the fact that some one else arouses in him the anger which follows upon the invasion of his rights and possessions. Jealousy may, therefore, be regarded as the first emotional expression of the growing feeling of self-importance.

As in the case of the other emotions, so in the experience of jealousy, there is no very clear intellectual apprehension of the relations that are involved. As soon as one comes to recognize clearly his rights and those of others, the tendency is for the emotion to give away, and for a fuller form of intellectual experience to arise. C. H. J.

**JEANES, ANNA T, FOUNDATION.** — An organization consisting of a board of trustees formed in 1908 for the purpose of admin-

istering the sum of \$1,000,000 left by Miss Anna T. Jeanes of Philadelphia for improving negro rural education. The aim of the board is to encourage and cooperate with established educational authorities without attempting to relieve them of the burden of responsibility. Thus the foundation steps in to point the way. At present its work lies in three directions: (1) the appointment of teachers to introduce and supervise industrial education (Hemico plan), (2) the appointment of teachers to do extension work among a number of schools and to act as supervisor, (3) the appointment of a county agent to improve the homes and the schools and to create a public sentiment for better schools, he also acts as a supervisor of schools. President Dr. James H. Dillard of Tulane University is general agent of the Foundation.

**JEBB, JOHN** (1736-1786). — Theologian, doctor, and university reformer, born at Cashel, Ireland; studied at Trinity College, Dublin, and Peterhouse, Cambridge, where he graduated B. A. in 1757, being second wrangler. He took holy orders in 1762, and continued at Cambridge as lecturer in mathematics and Greek Testament. In the history of Cambridge University (*qv*) he played a noteworthy part as the originator of a plan for examinations. In 1773 he brought forward a scheme for an annual examination in May of all undergraduates, including noblemen and fellow commoners. The subjects of examination were to be "the law of nature and of nations, chronology, history, classics, mathematics, metaphysics, and philosophy, natural and moral." These examinations were to be "preparatory to the more important Examination for the Bachelor's Degree." (See his *Remarks upon the present Mode of Education in the University of Cambridge . . . a Proposal for its Improvement*.) The scheme was rejected and a syndicate appointed to consider the scheme reported unfavorably. In 1774, however, he secured the appointment of a committee, "to draw up a plan for the improvement of the academic course of the university." A scheme for examinations was proposed by the committee, approved by the Caput, but lost by one vote in the Senate. The question called forth several pamphlets against Jebb, to which his wife Ann, who wrote frequently under the name of "Priscilla," replied. In 1771 he had taken an active part in promoting the petition to abrogate the rule requiring subscription of the Thirty-nine Articles on admission to the B. A. degree. In 1775 he resigned his clerical functions on conscientious grounds, and in 1776 he left Cambridge and took up medicine which he practiced in London. In

1779 he was elected a Fellow of the Royal Society. He was a friend of Priestley (*q.v.*), who dedicated to him his *Doctrine of Philosophic Necessity* (1777). In politics he supported the movement for Parliamentary reform and universal suffrage.

**JEFFERSON, THOMAS** (1743–1826) — Third President of the United States, “author of the Declaration of Independence, of the statute of religious freedom, and father of the University of Virginia,” according to the inscription on his tomb at Monticello, which he prepared before his death. He was graduated from the College of William and Mary in 1762, studied law, and was admitted to the bar in 1767. Two years later he became a member of the Virginia House of Burgesses. He took an active interest in scientific agriculture, and after numerous experiments he succeeded in domesticating many European shrubs and trees in Virginia. As a member of the Virginia legislature he secured the passage in 1776 of the statute of religious freedom, which abolished the connection between Church and State.

In 1779 he introduced into the assembly of Virginia a measure that contemplated the establishment of a state school system that should meet the needs of all the children. His measure provided for the division of each county of Virginia into hundreds, and the erection of suitable schoolhouses and the maintenance of schools by the hundred settlers. His measure was democratic in that it provided free schools for all classes, and it was in advance of the time in making the same provision for the education of girls that was made for the boys. Secondary schools were also contemplated in his scheme, in the organization of which three or more counties were to cooperate; and at the head of the entire system was to be the college. Thus the three great branches of education were to be unified, and through an ingenious system based upon the survival of the fittest, the brightest pupils in the elementary schools of the hundreds would pass on to the county secondary schools, and the brightest pupils in the secondary schools would ultimately reach the college. The college, which represented the choicest products of democracy, was to furnish the state with its leaders. Talent, he maintained, was always latent in the common people, and the scheme that he proposed aimed to bring the highest education within the reach of the poorest boy in Virginia. The measure did not become a law, but Jefferson never ceased to believe in its reasonableness.

He was subsequently sent to France to join Franklin and Adams in negotiating commercial treaties, and during his five years' European residence he studied with care the educational systems of the Old World, and by means of correspondence kept the American colleges advised with reference to educational movements, appliances, and publications. He wrote to President Washington from Geneva concerning the feasibility of removing bodily to Virginia the entire teaching staff of the Swiss university.

After nearly forty-five years of public life, Jefferson retired from the presidency of the United States in 1809 and devoted the remaining fifteen years of his life to education. The public school system, which he had advocated as a member of the Virginia assembly nearly a half century before, was taken up with fresh vigor, and the correspondence on the subject with Joseph C. Cabell, a member of the state legislature interested in educational matters, covers 528 pages. In one of these letters he says: “A system of general instruction which shall reach every description of our citizens, from the richest to the poorest, as it was the earliest, so will it be the latest, of all the public concerns in which I shall permit myself to take an interest.”

For nine years he labored earnestly with the legislature to secure the enactment of measures that would bring about a system of state education, such as he had proposed during the American Revolution, but the bills introduced by Cabell and other friends were successively defeated by one or the other branches of the Virginia legislature. Finally, in 1818, a bill was passed making an annual appropriation of \$15,000 for the maintenance of a university “wherein all the branches of useful sciences were to be taught,” with a special grant for the purchase of a site and the construction of buildings. Commissioners — including Jefferson, James Madison, and Joseph C. Cabell — were appointed by the governor, in 1819, to carry out the provisions of the law. Jefferson was selected rector, and “henceforth until his death in 1826,” remarks the late Professor Herbert B. Adams, “he was the directing and shaping power in the upbuilding of the University of Virginia. From his original and sovereign interest in university education, and from his residence in immediate proximity to the university, the other visitors were well content to leave to him practically the entire management of affairs. Not only did he evolve the entire system of education there introduced, but he actually devised every feature of construction and administration. He drew plans, made estimates and contracts, busied himself about bricks and mortar, and superintended the whole process of building.” (See VIRGINIA, UNIVERSITY OF; COLLEGE, AMERICAN.)

Jefferson's views on university organization

included: (1) the abolition of a prescribed curriculum and the adoption of an elective system, and (2) the reduction of discipline to a minimum, "avoiding too much government, by requiring no useless observances, none which shall merely multiply occasions for dissatisfaction, disobedience, and revolt." The purpose of a state university, as he saw it, was (1) to form the statesmen, legislators, and judges, on whom public prosperity and individual happiness depend; (2) to expound the principles and structure of government, the laws which regulate the intercourse of nations, those formed municipally for our own government, and a sound spirit of legislation, (3) to harmonize and promote the interests of agriculture, manufactures, and commerce, and by well-informed views of political economy to give a free scope to the public industry, (4) to develop the reasoning faculties of our youth, enlarge their minds, cultivate their morals, and instill in them the precepts of virtue and order, and (5) to enlighten them with mathematical and physical sciences, which advance the arts, and administer to the health, the subsistence, and comforts of human life. W. S. M.

**JENA, UNIVERSITY OF**—This university, which is under the joint control of the Grand Duchy of Saxe-Weimar, Eisenach, and the three Saxon duchies, owes its origin to a *Gymnasium* founded as a Lutheran seat of learning by the Elector John Frederick the Magnanimous in 1548. The institution was raised to the rank of a university by an imperial decree dated August 15, 1577, but the new university did not open its doors until February 2 of the following year. The dominant faculty for two centuries was that of theology, which at first reflected pronounced orthodox tendencies in contradistinction to the more liberal tendencies that flourished at the University of Wittenberg, but later became a center of rationalism. The halcyon days of the university fell between 1620 and 1720, when large numbers of students were attracted to its halls. Toward the close of the eighteenth century, Jena began to play a distinguished rôle in the field of philosophy, becoming a center for the dissemination of the theories of Kant, among its prominent teachers at this time being Fichte, Schelling, and Hegel. These were the days—the closing years of the eighteenth and the opening years of the nineteenth

century—when the Duke Karl August reigned in Saxe-Weimar. Goethe came to his court in 1775 and Schiller some years later, and the former took an active interest in the affairs of the university, while the latter taught history there for a brief space, all health compelling him to resign his chair. The activity displayed by Jena in the field of philosophy has been continued to the present day, Rudolf Eucken being at present head of the department. Jena is one of the few German universities at which emphasis has been placed upon the study of pedagogy, and the institution enjoys a well-deserved reputation in this field, the pedagogical seminar, in connection with which a practice school is maintained, being the first to have been established at a German university (1843). (See EDUCATION, ACADEMIC STUDY OF.) The political economy seminar, founded about the middle of the last century, was also the first of its kind. Among well-known former professors of the university may be mentioned H. Hettner in Germanic, Georg Ebers in Oriental, and August Schleicher in Indo-Germanic philology, J. G. Droysen in history, and Bruno Hildebrand in political economy. More recently Jena has come into prominence largely through the teachings of Ernst Haeckel, who has filled the chair of zoology since 1865. Another field in which the university has won, and is still winning, much renown is that of physics and mechanics, more especially optics, a considerable fund for equipment and research in this and related lines having become available through the generous gifts of Carl Zeiss, the optical manufacturer of Jena. The theory of the microscope was first developed in the mechanical laboratory of the University of Jena by Professor Abbe, and the optical laboratory of the institution is to-day the leading one of its kind in existence. The university also maintains an agricultural school, in contradistinction to the custom prevailing in Germany of making provision for this subject in separate seats of learning, the Jena school being the continuation of a private agricultural institute founded in 1826 by F. G. Schulze as the first agricultural academy. The university possesses a Germanic museum, a valuable collection of Oriental coins, as well as excellent geological, mineralogical, and zoological collections. Among the medical institutes may be mentioned one for hygiene and one for psychiatry. The nucleus of the library is the collection transferred from Wittenberg to Jena after the surrender of the former town in 1548 and presented to the university at the time of its foundation ten years later. It contains almost 1000 Mss., about 100,000 dissertations, and over 200,000 volumes. A group of new and up-to-date buildings was erected between 1905 and 1908. The annual expenditures of the institution amount to approximately \$160,000. In addition to the endowment provided by Carl Zeiss, which is

available for various purposes in addition to those mentioned above, other funds have been supplied by private individuals — until quite recently a rather rare phenomenon in German higher education, among which may be mentioned the fund donated by Paul von Ritter for research in the field of phylogenetic zoology. In 1815 there was established at Jena the first of a series of democratic student societies known as the *Burschenschaften* (*qv*), which later played an important part in the political affairs of the nation, Prussians being forbidden to attend the university from 1819 to 1825. (See *Die Gründung der deutschen Burschenschaft in Jena*, Jena, 1883.) In point of winter attendance Jena ranks fourteenth among the German universities, although at one time it was one of the most frequented. In the winter semester of 1911–1912 it attracted 1831 students, of whom 93 were auditors. As at so many other German universities, more than half of the matriculated students were registered in the faculty of philosophy (1010), medicine enrolling 356, law 302, and theology (Protestant) 70. A well-attended summer school, which attracts students from all parts of the world, is also conducted. The teaching staff consisted of 101 professors and 20 docents. R T JR

## JEROME, SAINT (HIERONYMUS) —

Early Latin Father, born at Stridon in Pannonia, about 340, died at Bethlehem, 420. About the year 360 he went to Rome, where he was baptized. Thence he went to the famous school of Trier, where he made his theological studies. After spending some time at Aquileia, he went in 373 to Antioch, and there he was ordained priest. In 381 he was at Constantinople, and in 382 he returned to Rome. There for three years he enjoyed the friendship and patronage of Pope Damasus. After the death of the pope in 384, he set out for Antioch, Alexandria, and Bethlehem. He reached the last named place in 386 and there he remained until his death in 420. His *Letter to Læta*, on the education of her daughter Paula is an important document in the history of early Christian education. Jerome advises that a teacher be selected who is of approved manner of life, of discreet age, and equipped with learning. The pupil, he says, should be given wooden or ivory letters and be taught their names. She should be encouraged both by healthy emulation and by games and amusements. She should not neglect the study of Holy Writ, but, beginning with the Psalter, should read the Proverbs, the Book of Job,

and the Gospels. As to dress and manners, she should never lose sight of the fact that she is consecrated to God. Her religious education is all important, and the mother is charged in conscience with the duty of supervising the child's education from day to day. Similar advice is given in the *Letter to Gaudentius* on the education of Pacatula. It should be remembered that the severity of life prescribed by Jerome is justified in his estimation by the wickedness of the pagan world from the contamination of which he strives to save the young Christian maiden. W. T.

## JERSEY, EDUCATION IN THE ISLE

OF — The first grammar schools date from the year 1496, when King Henry VII, by letters patent dated Nov. 15 confirmed the establishment and endowment of the free grammar schools of St Magloire (now St Mauncher) in the parish of St Saviour's, and St Anastace in the parish of St Peter's for the teaching of grammar and the 'other lesser liberal sciences'. The appointment was in the hands of the dean and clergy of the island, and this was confirmed by a decision of the Privy Council in 1693, when the right of appointment was claimed by Charles de Carteret, Seigneur of Trinity. Scholars from this school passed to the University of Saumur, and this practice led to the separation of the Church in Jersey from the Church in England. Despite the fact that in 1499 the Channel Islands were transferred by Pope Alexander VI to the diocese of Winchester, the Bishop of Coutances exercised ecclesiastical jurisdiction as late as 1550. By that date the Reformation had taken its effect in Jersey, but the connection with Saumur made it follow the line of the French and Scottish Calvinists, with the result that the Presbyterian organization was introduced and a synod held on June 28, 1554. In 1619, however, the episcopal order was restored, and a code of canons for the Channel Islands received the royal assent on June 30, 1623. Canons forty and forty-one provided that there should be a schoolmaster in every parish to teach the children "à lire, écrire, prier Dieu, répondre au Catechisme; les diront aux bonnes Mœurs, les conduiront au Presche, et Prières Publiques, les y faisant comporter comme ils appartient." These schools had long existed; and were officially recognized by these canons. In the meantime efforts had been made to bring Jersey into connection with Oxford and Cambridge, and Laurens Bandains founded scholarships for the purpose, having failed in Queen Eliza-

beth's reign to found a university college in Jersey. In 1637 the Archbishop of Canterbury founded at Oxford three fellowships for the Channel Islands, and a little later the Bishop of Winchester (Morley) founded five scholarships for the islands at Pembroke College, Oxford. Thus Saumur was abandoned, and the last English link with France broken. The Jersey elementary schools were in the eighteenth century better than those in England, and most people in the island could read and write. In 1836 the National Society began to make grants to Jersey schools, and elementary education followed the normal English lines. By a *Règlement* of Aug 9, 1872, when the Privy Council grants ceased, a system of education similar to that established in England by the Act of 1870 came into force

MONTMORENCY J E G DE *State Intervention in English Education* (Cambridge, 1902)

**JESUITS, EDUCATIONAL WORK OF: OR EDUCATIONAL WORK OF THE SOCIETY OF JESUS** — The Society, or Company, of Jesus, was founded by the Spanish nobleman Ignatius of Loyola. The name "Jesuits" was given the members of the Society of Jesus by the opponents of the order, and occurs as early as 1544. According to an English educationist, "since the Revival of Learning no body of men has displayed so important a part in education as the Jesuits" (Quick).

**Ignatius of Loyola** — Ignatius, or, as he was originally called, Imigo (after a Spanish saint Eneco), was born at the castle of Loyola, in Guipuscoa, one of the Basque provinces of Spain. The year of his birth is most probably 1491. Brought up in the house of a high official of Ferdinand and Isabella, the ambitious youth took service in the army, and in 1521, while among the defenders of Pampeluna against the French, was seriously wounded by a cannon ball. During the slow recovery the reading of the lives of Christ and the saints wrought a great change in the hitherto extravagant officer. Determined to abandon his worldly life, he retired to Manresa, where he spent some time in the practice of ascetical austerities, solitary prayer, and meditation on religious things. The inner experiences of this period of spiritual formation grew into the *Book of Exercises*. Through this little manual of practical asceticism Ignatius becomes one of the foremost religious educators of modern times, and in our own days continues to influence the spiritual training of hundreds of thousands of Catholics annually, in the so-called "retreats" and "missions." The "Spiritual Exercises" contained the germ of the future Society of Jesus. In 1523 Ignatius went to the Holy Land to devote himself there to a life of piety and labors for the conversion of the Moslems. Obligated to depart from

Jerusalem, he recognized the necessity of further studies, in order to be of greater help to others. At Barcelona he learned Latin among little boys, then went to the universities of Alcalá and Salamanca, 1526-1527, and finally to Paris, then the greatest center of learning in Christendom, where he studied philosophy and theology, 1528-1535. Although he took a creditable degree (M.A.), his distinction was less than that of the scholar than of the guide and ruler of men and of the skillful organizer. A band of able and devoted students had gathered around Ignatius at Paris (Faber, Navier, Laynez, Salmeron, Bobadilla, Rodriguez), and in 1534 at Montmartre, Paris, they took vows of poverty and chastity, besides the vow of going to the Holy Land and there leading a life in close imitation of the life of Christ. When they later found it impossible to embark for Palestine, they offered their services to the Pope. In 1539 they determined to form a compact religious order, and the outline of a constitution was approved by Pope Paul III in the following year. Ignatius was elected the first General of the order, and governed it till his death in 1556. He was canonized in 1622. The story of the life of St. Ignatius, especially the patience with which, in advanced age, he devoted eleven years to study, the careful deliberations and frequent consultations with others on important matters, are sufficient proof that he was not a mere "religious enthusiast," or a "visionary" (Macaulay). His work shows that he was a genius in the practical order, a man of "powerful gifts of intellect and an unusual practical foresight" (Littledale). But the most prominent characteristic of Ignatius was a burning zeal for the spread of Christianity and the religious and moral betterment of his fellow-men. Toward this end he directed his foundation, the Society of Jesus.

**The Society of Jesus** — The official title of the order is "Society of Jesus", but the name "Jesuits" was gradually adopted by its members and friends. Ignatius himself had used the Spanish word "Compañia," which might be translated "Regiment of Jesus." This term suggests the former military life and spirit of the founder and the active part which the order was to play in the service of the Church militant. It is, however, an erroneous opinion, held by many Protestants and some Catholics, that the Society was founded with the avowed intention of opposing Protestantism. Neither the papal letters of approbation nor the Constitutions of the order mention this as the object of the new foundation. In fact, when Ignatius began to think of devoting himself to the service of the Church, he had probably not as much as heard the names of the Protestant Reformers. His early plan was rather the conversion of Mohammedans, an idea which, a few decades after the final triumph of the Christians over the Moors in Spain, must have strongly appealed to the ardent and chivalrous Spaniard. It is a

remarkable coincidence that the name *Societas Jesu* had been borne by a military order approved and recommended by Pius II in 1459, the purpose of which was to fight against the Turks and aid in spreading the Christian faith. The early Jesuits were sent by Ignatius first to pagan lands or to Catholic countries, to Protestant countries only at the special request of the Pope, and to Germany, the cradle land of the Reformation, at the urgent solicitation of the imperial ambassador. From the very beginning of the order, the missionary labors of Jesuits among the pagans of India, Japan, China, Canada, Central and South America, were at least as important as their activity in Christian countries. As the object of the Society was the propagation and strengthening of the Catholic faith, it is evident that the Jesuits endeavored to counteract the spread of Protestantism. They became the main instruments of the Counter-Reformation, which may rightly be styled the Catholic Reformation; the reconquest of southern and western Germany and Austria for the Church, and the preservation of the Catholic faith in France and other countries were chiefly due to their exertions.

**Organization of the Society** — The object and spirit of the Society of Jesus are to be sought in the "Spiritual Exercises," which are the training school of the religious life of the Jesuits, and the Constitutions, which contain the laws of the order. The so-called *Monita Secreta*, or *Secret Instructions*, are spurious, and a libel on the order, composed by one Zahorowski, who had been dismissed from the order; this work has been styled a lampoon, an ingenious forgery, etc., by writers not friendly to the Society, as Dollinger, Reusch, Huber, Harnack, Littledale, and others. The Society has no secret doctrines, nor any teaching which is different from that held by the Catholic Church in general. The order is divided into provinces, which comprise the colleges and other houses within certain countries or districts. Several provinces form an assistancy, arranged according to nationalities, or geographical proximity; there are, at present, five assistancies: Italy (with five provinces), Germany (provinces: Germany, Austria, Hungary, Galicia, Belgium, Netherlands), France (with four provinces), Spain (provinces: Aragon, Castile, Toledo, Portugal, Mexico), England (provinces: England, Ireland, Maryland-New-York, Missouri, New Orleans, California, Canada). The superior of a province is called provincial, the head of a college rector, both provincials and rectors are appointed, for a number of years, by the head of the whole Society, the General. The General is elected for life by the General Congregation, which is the legislative assembly of the order, and alone can add to the Constitutions, change or abrogate them. This General Congregation consists of the General (or

after his death his Vicar), the Assistants (chosen by the previous Congregation, one from each assistancy), the provincials, and two special deputies, elected by each Province. The Congregation may even depose a General, for grave reasons, although such a step was never necessitated in the history of the order. Although the General possesses full administrative power, he is not an absolute ruler, the Assistants form his council, and the monarchical character of the government is tempered by various constitutional restrictions. The members of the order are divided into different classes or grades: the Professed Fathers, who, besides the three vows of religion, have made a fourth, of special obedience to the Pope in regard to undertaking foreign missions, the Formed Coadjutors, either spiritual, *i.e.* priests who have taken the final three vows of religion, or temporal coadjutors, *i.e.* lay brothers, engaged in domestic duties, the Scholastics, who after their first religious vows are engaged in studying or teaching, lastly, the novices, who devote themselves for two years chiefly to exercises of religion before taking their first vows. The Jesuit priests are admitted to the last vows only after a long course of studies and religious tests, the profession is granted only after from seventeen to twenty years of life in the Society. Before the suppression of the Society in 1773, the number of Jesuits had exceeded 22,000, in 1910 there were 16,293, of these 7848 were priests, 4385 scholastics, 4060 lay brothers. There is no class of lay affiliates, neither male nor female. The Jesuits are not monks, like the Benedictines, nor friars, like the Franciscans and Dominicans, but "Regular Clerics," or "Clerks Regular." St Ignatius introduced several innovations, deviations from the life of the older religious orders. Thus there was no common choir, no distinctive religious habit, no prescribed austerities; a special vow was taken not to accept any ecclesiastical dignities, except at the peremptory bidding of the Pope. All these features were intended to free the Society from whatever might be an obstacle in the way of active work.

**Object and Special Work of the Order** — The object for which the Society was instituted is expressed in the first papal approbation of the Institute in these words: "The progress of souls in good life and knowledge of religion; the propagation of faith by public preaching, the Spiritual Exercises and works of charity, and particularly the instruction of youth and ignorant persons in the Christian religion." This object is expressed in the Motto of the Society: *Omnia ad Majorem Dei Gloriam* (abbreviated O.A.M.D.G.), *i.e.* "All for the greater glory of God." Jesuit writers frequently designate the work of the Society as "apostolic," and this briefly expresses its character. In the occupations of the Society there is great variety, in fact, a universality, which

embraces all activities which can further the glory of God and the betterment of men.

**The Ratio Studiorum** — From the beginning education occupied a very prominent place among the activities of the order. Frequent mention is made in official documents of "teaching catechism to children and the ignorant, lecturing on philosophy and theology in the universities, and instructing youth in the grammar schools and colleges." In fact, education so largely prevails in the activity of the Society that it can be called in a special sense a teaching, or school, order. Of the ten parts of the Constitutions the fourth treats of studies, it is the longest of all, and its clear and practical arrangement is worthy of admiration. Successive General Congregations emphasized the importance of educational work, calling it a "special and characteristic work of the Society," "one of the most desirable and beneficial occupations." In the final vows the Jesuit promises to have "a particular concern for the education of boys." During the lifetime of St. Ignatius, colleges were founded in Italy (Messina, Palermo, Naples, the Roman and German Colleges), Spain (Gandia, Salamanca, Alcalá, Valladolid), Portugal (Lisbon), France (Billom), and the German Empire (Vienna, Ingolstadt). Others were established soon after the death of St. Ignatius, as Cologne, Munich, Prague, Innsbruck, Douay, Bruges, Liège, Antwerp, etc. With the increase of the number of colleges the want of a uniform and detailed system of education was felt more and more. Plans of study were drawn up in different places, but they were merely private works. During the generalate of Claudius Aquaviva (1581-1615), the educational methods of the Society received a definite shape. In order to ensure a certain universality and uniformity (which were needed because men were often sent from one country to another), and at the same time to profit by the educational experiences of different countries, six able schoolmen were selected from different provinces and nationalities (France, Spain, Portugal, Austria, Germany, and Italy) and called to Rome, 1584. For a year these men studied pedagogical works, examined regulations of the most famous colleges and universities, and considered the suggestions submitted by prominent Jesuit educators. In 1586 the report drawn up by this committee was sent to the provinces to be examined by at least five experienced men in every province. The observations and criticisms obtained in this manner were utilized in the drawing up of a second plan, which, after careful revision, was printed in 1591. For some years the practical working of this plan was watched, and in 1599 appeared the *Ratio atque Institutio Studiorum Societatis Jesu*, usually quoted as *Ratio Studiorum*. It was the result of careful and most painstaking labor, from the manner in which it was drawn up it is evident that it was the work

of the whole Society rather than of any individual.

*Sources of the Ratio Studiorum.* — The statement frequently made that the *Ratio* was modeled on the educational theories of the Spanish humanist Vives (*qv*), and the plan of studies of Johannes Sturm (*qv*), of Strassburg, needs considerable modification. Educational treatises and regulations were extensively consulted by the men who drew up the *Ratio, Studiorum*, and among the numerous documents examined was also Sturm's famous plan of studies. But Sturm acknowledges his indebtedness to the humanistic schools of the Netherlands, especially the celebrated school of the Brethren of the Common Life (*qv*) at Liège, of which he had been a pupil. Some of the ablest early Jesuits were natives of the Netherlands, or had studied in the schools of that country, which were among the best in Europe at that time. It is natural to think that these schools were the chief model for the literary course of the *Ratio* as well as of other systems and plans. In fact, several features common to the *Ratio* and Protestant schools were found in Liège and other humanistic schools, of the Netherlands. The method of teaching philosophy, the sciences, and theology was essentially an adaptation of the system prevailing in the University of Paris, where Ignatius and his first companions had studied. Still, as is clear from the description of the origin of the *Ratio*, the chief source was the collective experience of Jesuit teachers in various colleges and countries.

*Later Modifications.* — Until the time of the suppression of the Society (1773), the *Ratio Studiorum* remained, in all its essential features, the authoritative plan of studies in the schools of the Society. This does not mean that there was absolute uniformity in all colleges. The Constitutions and the *Ratio* repeatedly declare that, according to special needs and circumstances, changes may be introduced. In some countries the teaching of the vernacular language and the systematic study of history and geography were added to the original classical curriculum. Certain kinds of punishment, competition, and reward, popular in southern countries, were allowed to be abandoned in northern countries. The need of a more thorough reform was felt after the restoration of the Society (in 1814), as it was evident that the changed conditions of intellectual life demanded more radical modifications of the curriculum. Under the General Father Roothaan, the revised *Ratio Studiorum* was published in 1832. Nothing was changed in the fundamental principles, nor in the general mode of teaching, but innovations were made chiefly in regard to branches of study. Latin and Greek remained the principal subjects, but henceforth more time and care were to be devoted to the mother tongue and its literature, to history, mathematics, and the natural

sciences. For the teaching of physics and chemistry separate regulations were made, which are indicative of the broad and progressive attitude of the revision. "The theoretical treatment is to be supplemented by experiments, and as these sciences make daily progress, it is the duty of the professors to acquaint themselves with the latest discoveries, and to advance in their lectures as the sciences progress." Since 1832 the non-classical branches have been emphasized more and more, non-classical schools have been declared to be in accord with the work of the Society as well as classical institutions. In modern Jesuit colleges physics, chemistry, astronomy, geology, biology, physiology, and other branches are taught according to the established principles and methods of modern science. In the words of the present General of the Society (F. X. Wernz), "As the early Jesuits did not invent new methods of teaching, but adopted the best methods of their age, so will the Jesuits now employ the best methods of our own time." Undoubtedly, the Jesuits were always conservative and did not immediately adopt every educational experiment; nor were the changes which seemed necessary introduced with the same readiness and celerity everywhere. In some countries (as in Austria), the Jesuits adopted the system prevailing in the state institutions, nearly everywhere the Jesuit colleges adapted themselves, in a considerable degree, to the national schools and the prevailing educational currents. The last General Congregation of the Society (1906) gave official recognition to this tendency by the following important decree: "Under the present conditions a new revision of the *Ratio Studiorum* is not to be attempted. Not even the *Ratio* of Father Roothaan can be satisfactorily carried out, on account of the special needs of different countries. For this reason the provincial superiors, after consultation with their advisers and the most approved teachers, should devise plans of studies for their provinces, and for the various districts in which the same conditions prevail." There is, accordingly, no longer a uniform *Ratio Studiorum* in force, as far as subject matter and arrangement of studies are concerned.

*Contents of the Ratio Studiorum* — Theoretical discussions on the educational value of different branches and similar topics were contained in the trial *Ratio* of 1586, but were absent from the final *Ratio* of 1599. The latter document was rather a code of laws, a body of practical rules drawn up by practical teachers, a collection of regulations for the officials and teachers. I. Rules for the provincial superior; for the rector (president) in whose hands is the government of the whole college; for the prefect of studies, the chief assistant of the rector, entrusted with the direct supervision of the classes and everything connected with instruction; another assistant

of the rector, the prefect of discipline, responsible for all that concerns order and discipline. II. Rules for the professors of theology: Scripture, Hebrew, dogmatics, moral theology, ecclesiastical history, Canon Law. III. Rules for the professors of philosophy, mathematics, physics, and other natural sciences. IV. Rules for the teachers of the *Studia Inferiora*, the lower department, devoted chiefly to literary studies. Originally there were five classes in this department, later frequently six: the three (or four) "Grammar Classes," corresponding with a classical High School, then the class of Humanities (Freshman) and the class of Rhetoric (Sophomore). Latin and Greek were the main branches in this department; other subjects, as history, geography, antiquities, were taught, under the name of "accessories," in connection with the classics. In the course of the seventeenth and eighteenth centuries history and geography began to be taught as separate branches in many provinces, and graded textbooks — usually six small volumes — were used extensively in France and Germany. Treatises on the method of teaching history and geography were in the hands of teachers in the beginning of the eighteenth century. Foreign languages were taught early in various places, e.g. French and Italian at Dillingen since 1655. Mathematics and natural sciences were considered as belonging to the department of "Arts," and were taught in the course of philosophy, since the revision of the *Ratio* in 1832, also in the lower department. In 1843 the curriculum of the college of Fribourg in Switzerland, one of the model colleges of the Society, contained the following subjects in the lower department (high school): Religion, Latin, Greek; French, German (one obligatory), history and geography (in all classes), arithmetic, algebra, geometry; in the higher (college) department, besides philosophy physics, chemistry, astronomy, botany, zoology, mineralogy; plane and spherical trigonometry, higher algebra, analytical geometry, differential and integral calculus, philosophy of history, and an advanced course in literature. In addition to these obligatory courses, Hebrew, Italian, English, and Spanish were offered as electives. This is an instructive example of local adaptation and modification, which shows how misleading it would be to take the text of the *Ratio* as an absolute indication of what was actually taught.

Philosophy was regarded as the desirable crowning of general training for all, and an important preparation for strictly professional studies. The system followed in philosophy and theology was the scholastic, or rather "neo-scholastic," i.e. scholasticism as developed by the Post-Reformation Catholic teachers, particularly the great representatives of the Society: Suarez, Vasquez, Molina, etc. The old *Ratio* had prescribed Aristotle as the

chief guide and standard author in philosophy, "except where his teaching is contrary to the Christian faith, or the commonly accepted doctrine of the [Catholic] Schools." The revised *Ratio* no longer mentions Aristotle as guide, although his philosophy continued to be followed largely in logic and metaphysics. In theology St. Thomas Aquinas (*q v*), was "the proper Master, but not so as if no deviation from his teaching were permitted on any point," particularly in regard to questions treated more fully by later authors.

The *Ratio* does not contain any provisions for elementary education. The cause of this omission is not, as has been imagined, contempt for this branch of educational activity, much less opposition to popular instruction, but the practical impossibility of entering that vast field. The Constitutions and General Congregations declare elementary education to be "a laudable work of charity, which the Society might undertake if it had a sufficient number of men." As there was often a dearth of men even for college work, and as the whole training of the Jesuits fitted them better for higher education, it would be unreasonable to blame them for thus limiting their work. In places, however, where elementary education was much neglected, especially in mission fields, the Jesuits frequently devoted themselves to this work, employing chiefly able lay brothers as teachers.

**Character of Jesuit Education** — The following features may be mentioned as most characteristic of Jesuit education. First, it was a system, well thought out and well worked out, and that at a time when in most schools there was little system, although the Jesuits had largely borrowed from other men and institutions, they had done so intelligently, above all, they had unified and systematized educational principles and methods in a manner never done before. The many practical rules laid down for the different classes and teachers, the careful supervision, the close unity and centralization, could ensure efficiency even in the case of teachers of moderate talent, while to teachers of more than ordinary ability sufficient scope was left for the display of their special aptitudes. Provisions were made for systematic professional training of the teachers, as early as 1565 the second General Congregation urged the establishment of a special pedagogical "seminary" in every province. Literary, philosophical, and scientific training, although given not simultaneously, but successively, formed a fair combination, which avoided the one-sidedness of pure scholasticism, and the still greater one-sidedness of humanism, or of later purely scientific education. At a time when barbarous punishments were common in schools, the discipline of the Jesuit colleges was comparatively mild; corporal punishment was inflicted rarely and only under rigid precautions. Playing was encouraged,

and general attention paid to the physical welfare of the students. The teachers were urged to take an interest in all the concerns of the individual student, and much was expected from personal contact between teacher and pupil. All teaching was to be gratuitous, fees were not admitted until, in later times, the spoliations of Jesuit property and the absence of sufficient endowments necessitated the acceptance of tuition money. From its beginning the Society took a warm interest in needy talented students, and in many places founded and supported boarding houses (*convictus*) for them. The most important aim of education, the one emphasized for all grades, and in the rules for all superiors and teachers, is the moral and religious training. To this end were directed the teaching of catechism, the practice of receiving the Sacraments of Penance and Communion, the pious associations of students, called "Sodalities", even the classics were to become "Heralds of Christ," by being interpreted in the light of Christian revelation. The determination to safeguard Christian faith and morality explains the rigid exclusion of books inimical to revealed truth, and the careful expurgation of all obscene and vulgar passages from the pagan writers used as textbooks. In this there was a radical and intentional reaction against the paganizing tendencies found in such humanists as Valla, Poggio, Beccadelli, etc., and in many Renaissance schools. The educational ideal of the Jesuits was like that of the Brethren of the Common Life (*q v*), namely, piety adorned with learning, or culture on the basis of religion (*pietas literata*).

**Intellectual Scope and Methods of Teaching** — The intellectual aim of the literary course was that common to all humanistic schools, it has been well expressed in the two words "learning" (classical) and "eloquence" (*sapientia et eloquentia*). This meant the acquaintance with the thoughts of the classics, mastery of the Latin language, and the acquisition of a good Latin style. During the sixteenth and seventeenth centuries Latin remained to a great extent the medium of political and scholarly intercourse, hence it was of considerable practical use, and Protestant and Catholic schools alike aimed at imparting the mastery of it. This practical use, however, was not the only object sought in teaching the classics. In 1669 a French Jesuit educator wrote "Besides literary accomplishments gained from the study of the classical languages, there are other advantages, especially an exquisite power and facility of reasoning." Here we have an early expression of what now is called the theory of mental training, or formal discipline. This aspect of classical teaching was, naturally, more emphasized by Jesuits and other educators after the directly practical use of Latin could no longer be urged.

The means of acquiring a knowledge of the

classical languages was a carefully planned system of coordinate exercises: the "prelection," memory lessons, repetitions (daily, weekly, monthly, annual), compositions, disputations, contests, and examinations. The typical form of Jesuit teaching, the "prelection," is minutely described in the *Ratio*. It means "lecturing" in the higher faculties, its equivalent, *Vorlesung*, is at present used in German for the lectures in universities. In the lower grades it means "explanation," and is applied to the translation and interpretation of authors as well as to the explanation of the precepts of grammar, poetry, rhetoric, and style. One part of the prelection is called "erudition," which means the explanation of various details contained in the text: historical, geographical, archaeological, biographical, political, ethical, and religious. In the philosophical course the frequent disputations constitute the most important exercise. An inheritance of the medieval universities, they were retained for a long time also in Protestant institutions. In fact, the intellectual aims and practical methods were nearly the same in Protestant and Jesuit schools, the chief difference is found in the greater systematization and centralization of the Jesuit system. In both Protestant and Catholic colleges of former centuries the school drama was an important feature, in Jesuit colleges it was cultivated to a remarkable degree for the purpose of training in speaking and acting, and even more for religious edification and moral elevation. Not a few of the numerous Jesuit productions possessed more than ordinary dramatic value.

**Criticism** -- Few systems of education have been the subject of such conflicting valuation as that of the Jesuits. Many have praised it enthusiastically -- some even extravagantly; -- others, especially in recent times, have severely censured it. That extremes in this, as in other matters, are to be avoided is evident. The Society itself did not consider its educational system absolutely perfect, as is clear from the frequent inquiries about its working, from repeated requests for suggestions concerning improvements, and most of all, from the various revisions and gradual transformation of the system. Leading historians of the order (e.g. Duhr, *Geschichte der Jesuiten*, I, p. 259), admit that, especially in the old *Ratio*, there were defects, as the relative neglect of history, geography, and other branches, which were taught only as "accessories" to the classics. How this defect, common to all schools of former centuries, was gradually remedied has been mentioned before. Again, the old curriculum was, undoubtedly, too purely literary, too prominently classical, and neglected subjects which were rightly insisted on by the later "realistic" educators. Nor can it be denied that the humanistic conception of the importance of "eloquence and style" was exaggerated and one-sided, and was open to the charge

of excessive "formalism." Much, however, of current criticism of Jesuit education is due to misunderstandings. The very terminology of the *Ratio Studiorum* has led some into serious errors. Certain regulations, meant for the "Scholastics," i.e. members of the Society engaged in studies, have been interpreted as applying to other students. Many critics forget that educational principles and practices, established in the sixteenth and seventeenth centuries, should not be judged according to twentieth-century standards. There would be much force in such criticism, if all the older practices had been retained in the Jesuit colleges of our own days. Such seems, indeed, to be the conviction of some critics, as when it is asserted that "the *Ratio Studiorum* devised by Aquaviva is still obligatory in the colleges of the Society" (*Encyclopedia Britannica*, 11th ed., Vol. XV, p. 342). How little this accords with actual conditions is clear from what has been said on the modifications of the educational system of the Jesuits. Many secondary features of the *Ratio*, as the colloquial use of Latin, certain means of fostering emulation, the employment of boy monitors, have long ago been abolished in most places. A great deal might be said in defense of certain much censured features, e.g. emulation. "An excess was, perhaps, not always avoided; but it should be remembered that some emulation is indispensable in the schools" (Paulsen, *Geschichte des gel. Unterrichts*, Vol. I, p. 341).

In more recent years the Jesuit system has been censured for maintaining prescribed courses instead of a broad electivism, for retaining the classics and upholding the theory of mental discipline. These charges need not be discussed here, as they do not concern Jesuit colleges alone, the controversies on these points are not yet closed, but in the case of some, notably the question of electivism, there is a reaction toward the view defended by the Jesuits. Dr. Elmer E. Brown has well observed that in many of these controversies "the Jesuit side is the side of many who are not Jesuits" (*Educational Review*, December, 1904). The most common and most serious charge against Jesuit education is that it suppresses "originality and independence of mind." In reply, the Jesuits can point to the variety of scholarship found in their own midst, as well as to the great number of pupils who achieved distinction in most varied spheres of life: poets like Calderon, Torquato Tasso, Molière, Goldoni, orators like Bossuet, jurists like Pothier, the greatest French jurist before the Revolution, scientists and historians like Galileo, Cassini, Réaumur, Buffon, Lalande, Descartes, Muratori, Ducange. Father Porée, Voltaire's teacher, saw many of his pupils -- it is said nineteen -- elected members of the French Academy. It would be absurd to claim all the greatness of these men for the system under which they were brought up. Some Jesuit

pupils, as Voltaire and Lamarck, became famous for opinions which they had not been taught by their Jesuit masters. But this last fact seems to prove all the more conclusively that their originality was not crushed by the system. If, however, by "independence of mind" is understood unrestrained liberty of thought in religious matters, it must be admitted that the *Ratio Studiorum* and the whole Institute of the Society are uncompromisingly opposed to it, and that the Jesuits always endeavored to suppress it. For they are bound by their profession and fully determined to uphold, defend, and propagate revealed religion, as taught and interpreted by the Catholic Church. In this they do not differ from other religious orders, nor from any consistent Catholics.

#### Jesuit Schools before the Suppression —

For some time the Jesuits possessed almost the monopoly of higher education in various Catholic countries. On the eve of the suppression the Society had 669 colleges and a number of other institutions of higher learning, or, in round numbers, about 700 higher schools. Some of the colleges had more than 2000 students each, it is impossible to give an exact average, but 300 seems to be very low. Accordingly the 700 institutions would have numbered over 200,000 students, from which it follows that the educational influence of the Jesuits in those days was extraordinary. In Latin America alone there were 90 colleges, in the north was the flourishing college of Quebec (since 1635), and a report of 1711 states that there "grammar, the humanities, rhetoric, mathematics, philosophy, and theology are taught, perhaps with greater regularity, exactness, and fruit than in many colleges in France." Owing to the Penal Laws, which were especially severe and explicit in regard to the Jesuits, it was impossible for them to have schools with a full college curriculum in the English colonies. Still, they attempted to open higher schools when and where opportunity offered. Thus they had a classical school in New York for some time under the Catholic Governor Dongan, about 1684. In Maryland a school under their direction is mentioned at Newtown about 1640, and in 1677 a "school of humanities" was established, a Latin school of a preparatory character. In the midst of government opposition, legal penalties, and the hostility of part of the Protestant population, the Jesuits continued their educational activity in that colony for a long time. Before the middle of the eighteenth century their school was at Bohemia, Md. Georgetown (D.C.), which was opened after the War of the Revolution, may be regarded as a successor to Bohemia. Elementary schools were maintained in the Jesuit missions of South and North America. In the mission schools of Lower California, and especially of Paraguay, besides reading and writing, also music was taught and manual

training given. In Canada the Jesuits had established "Seminaries," i.e. elementary schools for European and Indian children, and they called religious women from France for the education of girls. After 1740 elementary schools were opened in various Catholic settlements, chiefly German, in Pennsylvania, of which the Jesuits had charge. "Tracing things to their commencement and their cause, we must attribute to the Jesuits, more than to any other single influence, the establishment of the Catholic school system, such as it exists to-day." It is principally to the Jesuit schools in Maryland and Pennsylvania that we owe the development of the Catholic parochial school system in the United States" (Burns, *The Catholic School System in the United States* pp. 89, 164).

#### Jesuit Schools in Modern Times —

The expulsion of the Jesuits from France, Portugal, and Spain through the absolutist Bourbon courts, and the suppression of the order by Clement XIV (1773) at one stroke annihilated the vast educational organization of the Jesuits in all parts of the world, with the exception of Prussia and Russia, where their schools were maintained by the express orders of two free-thinking rulers, Frederick the Great and Catherine II, because, as these sovereigns declared, the Jesuits were the best teachers available for their Catholic subjects. The suppression meant to the Jesuits the total loss of their colleges, libraries, observatories, and all property. After the restoration (1814) the order struggled into existence under very unfavorable conditions. There was hardly a year during the nineteenth century that the Jesuits were not harassed in one country or other, or even driven into exile. It is evident that such persecutions were most detrimental to educational activity, and they were the principal cause which prevented the Jesuits from obtaining results similar to those of former centuries. Still, the number of colleges has increased considerably, especially in English-speaking countries. At present the Jesuit colleges all over the world number about 225. In North America there are in Canada the colleges of Montreal (two) and St. Boniface (Manitoba), in the United States forty-one colleges, with over 16,000 students. Recently several American colleges have expanded into universities, with medical and law faculties, as Georgetown (D.C.), Fordham (N.Y.), St. Louis, and Omaha. In foreign countries the most prominent Jesuit schools are the Gregorian University in Rome (successor to the old Roman College, which, with its observatory, precious library, and *Museo Kircheriano*, was secularized by the Italian government), Stonyhurst (q.v.), Beaumont, Liverpool, Mount St. Mary's, Stamford Hill, Wimbledon (England); Clongowes, Dublin (2), Mungret, Limerick (Ireland), Sydney (2), Melbourne (2), (Australia); Grahamstown (South Africa), several institutions in Belgium;

Innsbruck (university), Feldkirch, Kalksburg (Austria), Kaloesa (Hungary); the university in Beyrut (Syria); Bombay, Calcutta, Trichinopoly (India); Manila (Philippines), Zi-ka-wei (China). In mission countries numerous elementary schools are under the direction of the Jesuits.

The following is a list of Jesuit colleges and schools in the United States.—

New York			
St Francis Xavier	New York City	1847	
Fordham University . .	New York City	1841	
Loyola School . . . .	New York City	1900	
Brooklyn College . . .	Brooklyn	1909	
Canisius College . . . .	Buffalo	1870	
Novitiate of St Andrew .	Poughkeepsie	1903	
Massachusetts			
Boston College . . . .	Boston	1864	
Holy Cross College . . .	Worcester	1843	
New Jersey			
St Peter's College . . .	Jersey City	1878	
Pennsylvania			
St Joseph's College . . .	Philadelphia	1851	
Maryland			
Loyola College . . . . .	Baltimore	1852	
Woodstock College . . .	Woodstock	1869	
District of Columbia			
Georgetown University . .	Washington	1780	
Gonzaga College . . . . .	Washington	1821	
Missouri			
St Louis University . . .	St Louis	1818	
St Stanislaus Seminary . .	Florissant	1823	
Ohio			
St Xavier College . . . .	Cincinnati	1831	
St Ignatius' College . . .	Cleveland	1886	
St John's College . . . .	Toledo	1898	
Michigan			
University of Detroit . . .	Detroit	1877	
Illinois			
Loyola University . . . .	Chicago	1870	
Wisconsin			
Marquette University . . .	Milwaukee	1864	
Sacred Heart College . . .	Prairie du Chien	1880	
Nebraska			
Creighton University . . .	Omaha	1879	
Kansas			
St Mary's College . . . .	St Mary's	1848	
California			
St Ignatius' College . . . .	San Francisco	1855	
Santa Clara College . . . .	Santa Clara	1851	
Los Angeles College . . .	Los Angeles	1911	
Sacred Heart Novitiate . .	Los Gatos		
Washington			
Gonzaga College . . . . .	Spokane	1887	
Seattle College . . . . .	Seattle	1892	
Louisiana			
College of the Immaculate			
Conception . . . . .	New Orleans	1847	
Loyola College . . . . .	New Orleans	1910	
St Charles College . . . .	Grand Coteau	1838	
St John's College . . . . .	Shreveport		
Alabama			
Spring Hill College . . . .	Spring Hill	1830	
Florida			
College of the Sacred Heart	Tampa	1899	
Georgia			
Sacred Heart College . . . .	Augusta	1900	
St Stanislaus College . . .	Macon	1887	
(formerly Pio Nono College)		1871	
Texas			
St. Mary's University . . .	Galveston	1854	
Colorado			
College of the Sacred Heart	Denver	1876	

**Literary and Scientific Activity.**—In connection with the educational work of the Jesuits brief mention must be made of their literary and scientific work, because it was largely done by college professors and is an indication of

their scholarly interests and attainments. The *Bibliothèque de la Compagnie de Jésus*, published by Sommervogel (1890–1909), contains in ten folio volumes the names of over 15,000 Jesuit writers and several times as many titles of works composed by them. Many of these treat of ascetical and theological subjects, and may here be left out of consideration, except the catechetical works of about 400 Jesuits, which, in numerous languages and editions, were a powerful means of religious instruction of youth. In particular, the catechisms of Peter Canisius and Bellarmine, were for centuries in almost universal use throughout the Catholic world; in recent times the catechisms of Father Deharbe obtained an immense circulation, not only in Europe, but also in America. A great number of the works composed by Jesuits deal with literary and scientific subjects. It is but natural to assume that in so vast a number there are many productions of not more than ordinary quality, but a respectable portion are of more than common, even of exceptional value. Not a few Jesuit writers have gained great distinction in various fields of scholarly activity, as some of their bitterest enemies are compelled to acknowledge. "In mathematics and natural sciences there are among the Jesuits writers who stand in the first rank" (Huber, *Der Jesuitenorden*, p. 418). And long before D'Alembert had written in a violent attack on the order "Let us add—for we must be just—that the Jesuits have successfully cultivated eloquence, history, archaeology, geometry, and literature. There is scarcely a class of writers in which they have no representatives of the first rank." Only a few names can be mentioned here: Beschi, Ricci, Prémare, Gaubil (oriental philology), Hervás (comparative philology), Tiraboschi (literary history), Petavius (chronology), Hardouin (history), the Bollandists (history and criticism), Kircher (various branches of learning), Clavius (mathematics and calendar reform), Saccheri (non-Euclidean geometry), Riccioli, Scheiner, Grimaldi, Boscovich (mathematics, astronomy, optics, physics), Secchi (physical astronomy and meteorology). Some of these men made important discoveries and through their researches have contributed to the advancement of science. With a considerable number of Jesuit colleges observatories were connected. According to Montucla, at the time of the dispersion of the Jesuits, 130 observatories existed all over the world. Of these thirty-two, *i.e.* one fourth, were directed by the Jesuits. At the present day, more than twenty Jesuit colleges possess observatories, astronomical, magnetic, meteorological, or seismological. Great services have been rendered to science and navigation especially by the meteorological observatories of Belén (Havana) and Manila.

**Summary**—Jesuit colleges and Jesuit education stand for a great deal more than mere

classical culture. There is reason to think that opposition to the religious principles of the Jesuits has prevented many critics from forming a correct appreciation of the educational work of the order. It should certainly be possible to separate clearly considerations of religious tenets from questions of educational methods and efficiency. This has been done by men like Bacon, Grotius, Ranke, and others, who spoke with admiration of the zeal and success of Jesuit educators. Of recent writers, who had judged with independence and fairness, it will suffice to mention Professor Paulsen, one of the greatest historians of education. "No one can doubt," he writes in his classic work on higher education, "that the *Ratio Studiorum* was worked out with extraordinary care and with much intelligence. Nor do I doubt that the order through its schools has effectually furthered the spread of intellectual culture, especially classical learning, in Catholic lands. The Jesuits were certainly the most learned and most zealous teachers that could then be had in Catholic countries. And that they were not unskilled teachers has been proved by their success" (*Gesch. des gel. Unt.* Vol. I, p. 423). In his last work the same writer adds: "The success of the order was brilliant, almost overwhelming, in two generations it had become 'the order of professors' in the Catholic world. One must, undoubtedly, assume that this success was, on the whole, gained through positive achievements" (*Das deutsche Bildungswesen*, 1906, p. 52). A system which produced such results must, from the beginning, have contained features of unquestionable merit. It embodied, says another writer, "much educational wisdom and experience, practical skill, and a pedagogical insight which never swerves from the main purpose" (Fleischmann). It contained much that is of permanent value in education.

### JEWISH EDUCATION — Ancient Period

— The Jews, long before any other nation of antiquity, formulated an educational ideal and expressed the aim of education in terms of character formation, based on religious and ethical principles. The product of a sound education was to be a God-fearing man (Deut. x, 12; Prov i, 7), for "the fear of the Lord is the beginning of wisdom." The Jews did not, as the Greeks, create God in the shape and with the qualities of man, but man was created in the image of God, and his ideal was to be found in God. Unlike their neighbors, even the most civilized, the Jews did not practice the exposure of children, for none was so unfit that it could not learn God. Indeed, the reward for true observance of faith was increase of progeny, "happy is the man that hath his quiver full of them" (Ps cxxvii, 5). Schools as such were unknown in Biblical times, because it was felt that the education of children was the business of the family. It was the duty of the parents to act as interpreters to their children of the annual festivals and the religious rites and ceremonies, all of which served as object lessons in the history of their ancestors and as practical religious and moral training (See, especially, Exod xii, 26, 27; xiii, 8, 14; Deut. iv, 9, 10, xxxii, 46, etc.) More particularly was it the duty of fathers to hand down the national traditions (Deut. iv, 19, vi, 6; Ps. xlv, 1; lxxviii, 3–6), and to explain local landmarks (Josh iv, 6, 21). But it is clear that the mother also had an important educational function (Prov. i, 8, vi, 20). That the welfare of the State depends on the well-being of the family was also recognized (Fifth Commandment). Reading and writing (Deut. vi, 9; xxvii, 8, Josh xviii, 9, Judges viii, 14; Job xxxi, 35, etc.), and sufficient arithmetic to calculate dates of festivals and everyday needs were included in the curriculum. History and songs formed part of the life of the nation. With the Jews, as with the Greeks, life was education, though the content was different. How strongly rooted the religious ideal of education was among the Jews may be gathered from the fact that, in spite of the material greatness and wide intercourse with the world, a worldly culture did not arise. Typical of the literature

of this period (c. 1000 B.C.) is the Book of Proverbs, the whole of which may be read as the expression of the educational ideals of the time, with its emphasis on the importance of both the father and the mother in the education of the child, with its stress on habit ("Train up a child," etc. xxii, 6); on the value of reproof as a mode of guidance (x, 17, xii, 1), on the importance of discipline and the rod of correction (xxii, 15, xxiii, 14; xxix, 15, etc.); and with its description of the virtuous woman (xxxii). The so-called "schools of the prophets," reputed to have been established by Samuel, were probably nothing more than associations of kindred spirits interested in the same work.

Under the influence of Ezra and Nehemiah the sacred writings acquired a new value and became an object of definite study. From this time on the Jews were the people of the Book. "The sacred writings became the spelling book, the community a school, religion an affair of teaching and learning" (Welhausen). A new class of instructors (*Sopherim* or Scribes) arose, as opposed to the Levites or official interpreters. The synagogues at a later date became places of instruction and discussion (cf. Philo, and Matth xxi, 23, Luke ii, 46, etc.) Ezra is credited, but on little authority, with the establishment of a school system. In the second century B.C. Hellenistic influence made itself strongly felt among the Jews. Greek customs and a gymnasium were introduced into Jerusalem (1 Macc i, 14, 2 Macc iv, 9, 12). This, indeed, is the first reference to physical exercise, although young men over twenty were expected to bear arms (Numbers i, 3, xxvi, 2; and later 2 Chron xxv, 5). The sages recommended the study of Greek and even the translation of the *Torah* into that language, because "only by Greek can it be adequately rendered." Furthermore, Greek was taught to girls as an accomplishment, although as a rule girls were only trained in household work and the duties of motherhood. It is not necessary here to do more than refer to the intellectual influence of the Hellenized Jews, for example, in Antioch and Alexandria, where Greek was more familiar than Hebrew, or to the merging of Greek and Hebrew philosophy and early Christian doctrine into the school of Neoplatonism. Nor was this contact with the world around a very late development, Theophrastus speaks of the Jews as a race of philosophers (*φιλόσοφοι τὸ γένος ὄντες*).

That the education of children was almost wholly domestic has already been mentioned. But the problem of the education of orphans had to be faced, and about 70 B.C. an educational system was established by Simon ben Shetach in Jerusalem, with compulsory attendance. The details of this law cannot be traced, but it seems highly probable that the education of orphan children of sixteen years of age was

intended. A century later, however, the High Priest, Joshua ben Gamla, passed a law providing for the establishment of elementary schools, with compulsory attendance from the age of six. Attendance before that age was strongly discouraged. Children would come to school equipped with a knowledge of reading, of some extracts from the Pentateuch, and the ceremonies learned from the father. By this law each community had to provide a teacher for every twenty-five children, with an assistant if the number rose to forty, and another teacher if the number reached fifty. The curriculum was religious, consisting of the Scriptures and anything arising out of this in the way of arithmetic, history, geography, and general knowledge. Josephus (*Contra Apion*, I, 12) says "Our chief care of all is to educate our children," and elsewhere (*ibid* II, 18) "from their earliest consciousness they had learned the laws so as to have them, as it were, engraven on their souls." The last statement is corroborated in almost similar terms by Philo (*Legat ad Gaium*, sec 31). How successful the system of education was may be shown by the testimony of Josephus (*Vita*, 2), who declares that at fourteen he could expound the most abstruse questions of law, a fact which may be confirmed by reference to the story of the Christ Child in the Temple (Luke II, 46, 47).

*Academies* — One of the most interesting illustrations of the influence of education on the survival of a nation is that presented by the Hebrew academies (*Beth hamidrash*). The synagogues had already been centers of study, probably from the time of Ezra, for in addition to the prayers, passages from the Holy Writ were read and explained to the people. After the destruction of the Temple Johanan ben Zakkai obtained permission from Vespasian to establish an academy at Jamnia or Jabneh, which became the new center for Jewish life. Here the traditional literature and laws of the nation were discussed, legal and ritual questions were decided, contradictions in the law were settled; theoretical and hypothetical questions were considered at length, and the foundation for future development was laid.

Under Gamaliel II the academy at Jabneh acquired great influence. Young men flocked here for training and ordination as rabbis, with power to teach, judge, and, with limitations, to decide on questions of ritual. Other academies sprang up at Lydda, Bekei, Usha, Sepphoris, Caesarea, and Tiberias. With changing political conditions and the eminence of the teachers, the influence moved from one place to another. The right of ordination was at first vested in the patriarch, whose office was hereditary in the house of Hillel, but later was exercised by the patriarch and council. A formal order and routine gradually sprang up according to which the privilege of speech was regulated and ranged from the president of the academy (*Rosh Yeshibah*) through the sages and

ordained students to the unordained disciples or candidates (*haberim*), with the power to sum up reserved to the president. In this way was accumulated the lore which for many generations was handed down orally. Since hardly any limits were set to the discussions, almost every field of knowledge was touched upon, including theology, philosophy, mathematics, astronomy, astrology, medicine, geography, history, architecture, botany, and animal anatomy, etiquette and manners were also discussed. By 219 these traditions were collected by Rabbi Jehuda Hanasi (the Prince), head of the academy at Sepphoris, and formed the *Mishnah*, a word literally meaning "teaching," and applied to the laws and regulations. At Tiberias the foundations were laid by Johanan ben Nappaha (A.D. 189–279), the founder of the academy, for the work which was finally compiled in the fifth century as the Jerusalem *Gemara*, or supplement of the *Mishnah*, consisting of supplements, discussions, and elaborations of that work. The academy at Tiberias flourished with brief intervals to the time of Saadia. The teachers at the academies bore different names at different periods, up to the compilation of the *Mishnah* they were known as *Tanaim* (teachers), during the development of the *Gemara* they were called *Amoraim* (speakers), later the name was *Saburaim* (examiners or investigators).

At the same time a parallel development was going on among the Babylonian Jews, where the academies became important about 219 A.D. Sora and Nehardea were the chief centers at first, but the place of the latter, on its destruction, was taken by Pumbeditha. At Sora originated the Babylonian *Gemara* under Ashi (d. 427). This work during its compilation was submitted treatise by treatise to the assemblies for discussion and criticism, until it was completed in the sixth century by the *Saburaim*. The Babylonian academy was called *Metibta* (meeting or session), or *Yeshibah*, the one being the Aramaic, the other the Hebrew name, and the head was called *Resh metibta* or *Rosh yeshibah*. At first the title of *Gaon* (Excellency) was given to the head of the academy at Sora, but was later bestowed on other eminent scholars. Sora was surpassed in importance in the eighth century by Pumbeditha, which continued successfully until it was brought to a close on the death of Hai Gaon (1038). An interesting institution connected with the Babylonian academies was the *Kallah*, a general assembly meeting twice each year, at the end of summer and winter, and not unlike the modern institutes or Chautauquas. A treatise, previously announced, was prepared by the disciples and discussed at the *Kallah*, the assembly being seated according to rank and a definite procedure being followed. All present were questioned individually by the president. In addition to the prescribed work, questions from all parts were discussed,

and the answers were formulated by the president. And these questions came from wherever Jews had settled, for the Babylonian academies had during the Gaonic period (from the seventh century on) surpassed and taken the place of those in Palestine, and it was not until the tenth century, when Moses ben Chanoch, himself a student of Sora, founded an academy at Cordova, that the Western Jews became independent of the East.

The two compilations, the *Mishnah* and *Gemara*, dealing with the laws and regulations and the exegetical discussion that had grown up around them, were known as the *Talmud*, which for many centuries remained the storehouse of Jewish learning and the center of Jewish intellectual activity.

**Educational Theories in the Talmud** — The theory of education in the nine centuries following the Old Testament period are to be found scattered in the Talmud. Education, meaning, as always, religious education, was regarded as the business of life. The ignorant man, the *Am ha'arez*, was to suffer civil disfranchisement and social ostracism, for the ignorant man cannot be religious, while "whoso knows the Bible, *Mishnah*, and morals will not sin easily." Hence the school was as much a requisite in every community as a synagogue, and to live where there was no school was forbidden. "The world exists by the breath of the children in the school." The importance thus attached to education explains also the reason why teachers were regarded as "the protectors" of a town. But the maintenance of schools was not a matter of importance to the individual alone, but also to the nation; and on these grounds the Patriarch in the fourth century sent two inspectors of schools up and down the country. The first and last duties of the father were to care for the education of his children, duties in which the mother also participated to some extent, and it was in the home that children first learned the meaning of the religious ceremonies and rites. The education of the child by the father began as soon as he could talk. In some communities infant schools (*Makri Dardeki*) were maintained, and received children at the age of five. Here the alphabet was taught, mainly through play and fanciful stories attached to each letter. But generally it was not considered wise for their future development to send children to school before the age of six, when they were admitted to the public schools, which were under the care of a publicly paid *Melamed Tinkoth* (teacher of children). But how intimate the relation between the home and the school was is evidenced by the fact that it was always the father, and not a slave, who took the child to school; while it was not unusual to supervise the work done at home. Great care was to be exercised in the selection of a teacher. The first qualification was an acquaintance with the whole store of learning. The teacher was to be married,

not young, patient and wholly devoted to the needs of his pupils, for a dishonest teacher was regarded as "of those of whom it is said, 'Cursed be he who doeth the work of the Lord deceitfully.'" Teachers were exempt from taxation, and, although those in the lower grades were paid a salary, it was very general for the teachers of the Talmud to follow some vocation; so Rabbi Johanan was a shoemaker, Rabbi Simon a weaver, Rabbi Joseph a carpenter. The reverence with which teachers were regarded is reflected in their titles, "Lights of Israel," "Princes of the people," "Pillars of Israel", and more respect and service were due to a teacher than even to a father, for "the father gives the son only temporal life, but the teacher helps him to obtain eternal bliss." Women could in no case be employed as teachers. Their sphere was the home. The pupils attended school morning and evening for five hours each day. The Sabbath and festivals were employed for review and examinations. Vacations were, accordingly, unknown, the only concession being a reduction of one hour a day during the heat of summer.

A well-defined school procedure came to be recognized, and a traditional curriculum was early established. The school age (five or six to fifteen) was divided into three periods — one devoted to the Scriptures, one to *Mishnah*, and one to *Gemara*. At thirteen boys were confirmed and attained their religious majority. The subjects mentioned formed but the core of the studies, the extent and scope has been described above in dealing with the development of the Talmud. The method, as usual with oriental peoples, and as is to be expected from the lack of written material, was wholly oral. The teachers, however, frequently wrote out sections for their pupils to read. The pupils sat on the ground or on benches around the teacher, and repeated their tasks aloud and articulately, for "to speak aloud the sentence which is being learned fixes it in the memory." Since so much of the work was a matter of memorization, numerous mnemonic devices were introduced. Among these may be mentioned acrostics, the arrangement of sentences in alphabetical order; the alphabet itself was learned in different arrangements forward, backward, grouping by twos taken from each end (a system borrowed from the Greek, *εγ αω, βψ*); numerical symbols were also used. But above all stress was laid on repetition, and teachers were recommended to repeat with their pupils until they mastered a subject thoroughly. Wholesale reviews and revisions were frequent in order to fixate the larger topics. At the same time it was not desired so much that the amount of information imparted should be great, as that a pupil should become the master of what he knew, and if a pupil failed to comprehend, the charge was laid to the teacher. But diligence and industry were expected from the pupils, and he who

said, "I have taken pains and acquired nothing," was not to be believed. The pupil was expected to ask questions, for "whoso is ashamed to question, learns nothing," and again "one who is bashful cannot be learned." Of classroom devices to stimulate the pupil there was no lack, emulation and rivalry being the chief of these. Sweetmeats and cakes, on which were inscribed words or whole sentences, were given to the younger pupils for good progress, while corporal punishment with a strap was inflicted for misbehavior or laziness. Older pupils were reprimanded or rebuked for breaches of discipline. On the whole, while teachers were expected to be stern, a certain degree of respectful intimacy between them and their pupils was recommended. The honor of a pupil was to be as dear to a teacher as his own. Mutual instruction and the instruction of backward children by an older boy, usually the head of his class (*Resh Duchna*), was a well recognized principle. In this way the teachers were relieved where classes were large, and a new stimulus was added, for "as a small chip of wood sets fire to a large one, so the younger pupils sharpen the older, or just as steel whets steel, so is one scholar sharpened by another," a principle which was rediscovered by the Jesuits. Further, intercourse with the learned was enjoined, since "even the ordinary conversation of the wise is instructive," or, as Rabelais puts it, "haunt the company of learned men."

The Talmud divides students into four categories, which "correspond respectively to a sponge, a funnel, a strainer, and a sieve," and develops the analogies. In another passage, which deserves quotation, it is stated that "four characteristics are found among the disciples. The first quickly comprehends and quickly forgets, such an one loses more than he gains. The second with difficulty comprehends, but does not readily forget, he gains more than he loses. He who comprehends quickly, but does not easily forget, has a goodly portion. He who slowly comprehends and forgets quickly has an evil portion." How the psychology of memory was developed has already been described. The connection between knowledge and conduct was emphasized, and the value of the impressions gained was measured by the expression in behavior. "Great is the study of the law, for it leads to action," and again "Not theory but practice is the important thing." And if the value of knowledge lay in its use, not the least service of the learned man was to teach others.

Intellectual training did not complete the education of children. Vocational preparation was not neglected, and this duty was enjoined on the father as much in the interest of society as of the individual, for "whosoever does not teach his son a handicraft, teaches him to be a thief," and again "learning, no matter of what kind, if unaccompanied by a trade, ends

in nothing and leads to sin." That "labor honors the laborer" has been shown by reference to the many scholars who were humble artisans. Fathers were also charged with the duty of the physical training of their children in so far as they were advised to teach them swimming.

Such was the educational tradition established by the Talmud. Modifications were made, but the spirit remained unchanged up to the present day. While there is some danger in attempting to read into the system what is not to be found therein, there is as little justification for dismissing, as some German writers have done, the educational theory of the Talmud as entirely valueless, because it did not have any historical influence. The reason for this, however, does not lie with the system, but in the fact that no trouble was ever taken to learn from a people which was regarded with contempt.

**Middle Ages — Spain.**—Few nations have responded so readily to external conditions as have the Jews, so in cosmopolitan Spain of the early Middle Ages their intellectual interests were as broad as the field of knowledge, and resulted in a profound influence on European thought, in Italy they showed the same light-heartedness, the same worldly spirit as their neighbors, while in Germany there is noticeable that strong moral and religious atmosphere, mystical tendency, which marked the Teutonic people.

For three centuries (sixth to ninth) there had been intellectual stagnation until the admission of Arabic influences gave rise to a new development, and a revived attention to the Talmud from a new point of view. Philosophy was called in to the support of the national religion. There arose an army of scholars, grammarians, astronomers, historians, philosophers, and poets, and with the new studies came a renewed interest in the education of children, and the formulation of educational theory to meet the new requirements. The educational ideals of the time (from the tenth to the thirteenth centuries) are indicated in letters, wills, and monographs. The best illustration of these is the will of Jehuda ibn Tibbon (1120-1190), a doctor and translator of philosophical and grammatical works. He had provided his son with a well-stocked library, with several editions of each book, and had engaged a teacher for him in secular subjects, the son is advised to study Arabic and Hebrew, orthography, grammar, and style, religion and medicine, he is to learn by teaching, to take pride in his library and be ready to spread knowledge by lending books willingly (the last recommendation is repeated frequently in other works of a similar nature as an act of piety). The highest point in the development of Hebrew-Arabic culture was reached in the time of Maimonides (*qv*), who attempted to reconcile Platonic philosophy with the Hebrew religion in the *Moreh Nebukim* (Guide of the Perplexed), which with his *Codex of the*

Talmud exercised a great influence on Hebrew study. Works on method of instruction and programs of study are now frequently met with, either original or based on Arabic sources. So Jehuda Charisi in the *Moral Sayings of the Philosophers* recommends ten subjects for a ten-year course: writing, grammar, and prosody, law or religion, arithmetic, mathematics, astronomy, medicine, music, logic, philosophy. These studies, however, always presupposed the Talmud and the Bible, which indeed formed a foundation. The best exposition of the ideas of the time is found in the *Healing of the Souls* by R. Joseph b. Jehuda Akinin of Barcelona (end of twelfth century). It is clear from this work that, as in Europe generally, so among the Jews, the influence of Aristotle led to an encyclopedic study. Numerous encyclopedias were written or translated in the twelfth and thirteenth centuries. Akinin's curriculum included reading and writing, the Pentateuch and *Mishnah*, grammar and poetry (carefully selected for its influence on character), Talmud, which must be memorized and thoroughly understood before proceeding to philosophy, including mathematics, natural science, and metaphysics. Philosophy is to be studied as a defense against heresy and for the prevention of error. Logic, dialectic, rhetoric, and poetics find a place, and Aristotle is the textbook. Mathematics includes geometry, astronomy, optics, music, and mechanics. Under natural science come medicine and the eight divisions given in Aristotle's *Physics*. Each study is justified on Biblical authority. No better description of the qualities of a teacher can be found than those given by Akinin. He must have full knowledge of his subject and critical ability, and knowledge must be the mainspring of conduct; he must treat his pupils as his sons and through knowledge lead them to right conduct; he must teach step by step according to the ability of his pupils, and teach them that learning is its own reward. The pupil must respect his teacher more than his parents; he must be ready to ask questions; he must let nothing distract him from his studies, beginning with the first principles; he must leave no point in his course unsolved; and he must leave his home to find the best teachers and the soundest learning. It is not necessary here to point out the analogies between the attitude toward philosophy and the curriculum here described, and the seven liberal arts and the aim of philosophical study in the scholastic period.

The change in political conditions, the expulsion of the Arabs, and the persecutions under Christian rule, combined with internal disputes, led to a decline in Jewish studies. In many places the rabbis forbade the study of philosophy at about the same time as the works of Aristotle were burned at Paris. Mysticism on one side or rationalism on the other, with a consequent contempt for religious prescrip-

tions, took the place of a study of philosophical foundations. It even became a matter of pride to admit ignorance of the sciences. Attempts were made here and there to revive secular learning, as by R. Jehuda b. Samuel b. Abbas (*Jair Natib*, or *Light of the Way*, c. 1250), by Schemtob b. Joseph Falaquera (c. 1290), by Abraham ibn Chasday (c. 1250), but with little avail. The reaction was complete in non-Arabic Spain and the Provence. While the study of philosophy was forbidden because it led to contempt for religion, justification for it was sought, as by Joseph Kaspi of Argentières (c. 1322), by claiming Hebrew origin for Aristotle's works and reaching into them commands to fulfill the words of the Hebrew teachers and prophets. As with scholasticism, so with Hebrew studies, ignorance began to cover its defects by disputations, by quibbling, and by strawsplitting; the spirit of the law was forgotten in a mass of petty details, novels, and commentaries. By 1350 Profiat Duran of Catalonia, although he himself had enjoyed a broad education, felt that the only way out of the confusion which had been wrought was a return to the traditional Hebrew curriculum. Hence his grammar (*Maase Efod*), which contains a number of pedagogic principles, omits all mention of secular studies.

As a general rule children received their education from private tutors, although every community maintained one or two public teachers. The practice of receiving payment for teaching became common in the twelfth century, as it was more and more impossible to combine a trade with the professional work. Maimonides rebukes teachers for receiving pay and scholars for accepting stipends and board. The teachers were always exempt from taxation. Instruction began at three or four, the child being introduced to his studies with ceremonials. Discipline as a rule was mild, rebukes being preferred to corporal punishment; fruit, clothing, and toys were used to stimulate the future scholar. While girls were excluded from schools, they learned the Hebrew language and prayers. Higher studies were pursued in the academies or public school-houses of the rabbis, the synagogues being also used. It became a matter of distinction for wealthy men to maintain academies at their expense, as it was also to possess a library and to be willing to lend books. The young men wandered from academy to academy in search of knowledge, many going as far east as Palestine and Babylon.

*Northern Europe.*—The Jews were long settled in the north of France and in the Rhine districts, their settlement having been encouraged by Charlemagne, who himself employed Jewish physicians and ambassadors. For several centuries they were allowed to live undisturbed and maintained friendly relations with their neighbors, as may be indicated in

France by the numerous fables (*Contes et Fabliaux*), both original and translations from the French, and in Germany by the use of the vernacular and the many popular translations or transcriptions into Jewish German dialect, while the troubadour, Susskind von Trimberg, could hardly have been an isolated instance of the part played by Jews in the literature of the homes of their adoption. The Crusaders, ecclesiastical decrees (e.g. that of Archbishop Odo of Paris, 1197), and the Black Death tended to destroy these relations, and the persecutions and intolerance broke up the Jewish homes and drove them to other settlements. Removed as they were from the Arabic influences, the northern Jews tended to remain largely in the traditional groove of intellectual activity, — collecting, editing, and commenting on the Bible, the Talmud, and other exegetical works. Epoch-marking was the work of R. Solomon b. Isaac, better known as Rashi of Troyes (1039–1105), whose summary, written in a simple, natural style, served as a useful school textbook to introduce students to the commentaries. This work was also used by Christians, so by Nicholas de Lyra, called the ape of Rashi, and by Luther.

The aim of Hebrew study at this time was to relate the Talmud to the changed conditions of life, and so new decisions and ordinances (*Tossafot* and *Tekanol*) were issued. While there is little on educational theory at this time, practice hardly differed from that among Jews elsewhere. The child was entered at school or with a teacher at Pentecost with a ceremony in the synagogue, and the teacher at once gave him his first lesson on the alphabet from a tablet smeared over with honey to denote the sweetness of learning, a cake, inscribed with several Biblical verses, was given to the young scholar, there were also other symbolical ceremonies. The curriculum differed but little from the traditional Bible, *Mishnah*, and Talmud, and Rashi. When the pupil had gone through these studies, it was usual to wander round to other teachers to learn the latest and most authoritative decisions and supplements (*Tossafot*), and many communities established houses of learning or academies (*Beth hamidrash*), and often provided board and lodging for wandering students.

It was in the north, and especially Germany, that the wandering spirit attained its greatest development among Jewish as well as Gentile students. The former (the *Talmud-bahur*) was more fortunate than his brother, for regular provision was made either in the *Yeshubah*, or academies, or in private houses for their reception and entertainment. But they suffered much privation and want in spite of this. The chief desire which inspired the wanderers was to hear some new explanation, some new decision. These scholars performed a service by making copies of, or in some cases stealing, works and thus circulating them, and by

spreading the new decisions and thus subjecting them to thorough criticism. It is not surprising that in time the value attached to "novels" led to hairsplitting disputations for their own sake and neglect and ignorance of the Bible and Talmud, features for which analogies can easily be found in later scholasticism.

An extremely interesting type of educational literature was produced by the northern rabbis which finds its analogy in the contemporary Books of Virtue, of Manners, and of Etiquette. But the distinguishing mark of the Jewish works is that they were addressed to the masses, while the chivalric books were intended for the gentry and noble. At a time when the canons of chivalry make almost no mention of learning, the *Conduct of Life*, contained in the will of R. Elieser of Worms (c. 1050) addressed to his son, emphasizes the importance of knowledge and piety, respect for learning and reverence for the teacher, intercourse with the wise, upright dealings with his neighbors of all religions; kindness to those in trouble and charity to the poor, and does not omit to give practical hints on hygiene and diet. Similarly R. Elasar of Worms (d. 1298) urges piety and humility, observance and knowledge of the Law, uprightness and love of neighbors, self-denial and kindness to the needy, constant study, and care for the education of children. The most complete work of this type is the *Book of the Pious*, attributed to R. Jehuda Chassid, a mystic of the thirteenth century. Here are emphasized neighborly love, upright dealings; kindly treatment of inferiors and animals, true piety and charity, education of children, boys by teachers and girls by their parents, separation of good and bad children, of bright and weak pupils, readiness to lend books and manuscripts, reverence for and care of sacred books. How the tradition was maintained is indicated in the *Book of the Pious* (called the "short" to distinguish it from the earlier work) of R. Moses Kohen b. Elasar of Coblenz (c. 1473), and in the anonymous *Book of Morals* (c. 1400), which was translated into the Jaigon in 1542. While both works repeat the emphasis on the qualities already mentioned, there are additions on table manners and etiquette in daily intercourse. Works of a similar character are found frequently throughout the sixteenth and seventeenth centuries, adequate testimony to the perennial interest in education.

**Hebrew Influence in Middle Ages** — In the early part of the period under consideration, that is, about the ninth and tenth centuries, Jew and Christian lived amicably side by side. Synagogal and church melodies were exchanged, and many Christian scholars used Hebrew words in commentaries. There was an interchange of thought on religious questions, and disputations appear to have been frequently engaged in. Aleinu refers to a disputation at Pavia about 800 between a Jew,

Julias, and Peter of Pisa. In the tenth century Rathernus, Bishop of Verona, defends his anti-Jewish attitude on the ground that the Jews were too outspoken in disputing with Christian theologians. The traditional training of the Jews afforded them a preparation for disputative argument which frequently led them to victory. Indeed, such was the confidence in their powers, that they were often the challengers. It is not surprising, then, to find that toward the end of the twelfth century the Church began by forbidding laymen to enter into theological discussion with Jews, and soon forbade such intercourse even to the somewhat better educated clergy. On their side, the Jewish rabbis used their influence to prevent such disputations when the era of persecution began (Cf. *Book of the Pious*). The friendly relations which existed between Jews and Christians not only led to disputations, but many of the clergy seized the opportunity to learn Hebrew from their Jewish friends, and there appears to have been an interchange of church and synagogal melodies. But the Church put an end to such tendencies to tolerance, holding *quoniam dispar est cultus, nullus debet esse amorum consensus*.

In two fields of study — medicine and astronomy — the Jews of the Middle Ages were preeminent, and their influence is strongly marked. The profession of medicine was almost wholly in their hands from the ninth to the thirteenth centuries. At Salerno there were in the early beginnings many Jewish teachers, and Hebrew was one of the languages in which lectures were delivered. The first medical encyclopedia (*Compendium Salernitanum*) was composed by Copho, who is thought to have been a Jew. From Salerno the Jewish doctors spread throughout Italy and held many important positions in ecclesiastical and secular courts, e.g. Farragut and Charlemagne, Zedekia and Charles the Bold. The *Canon* of Avicenna was first made accessible by a translation into Hebrew, and a commentary on Hippocrates was written in the thirteenth century by Abraham Cabrit. At Montpellier a Jewish medical school, the forerunner of the later university, was opened about 1025; and later, many Jews were connected with the medical faculty as teachers and as deans, until a ban went out in the thirteenth century against Jewish doctors.

In astronomy the Jews were active practically and theoretically. They made several astronomical tables, e.g. the Toledo tables in 1080, and the Alfonsine tables under the superintendence of Isaac ben Sid. Levi Gerson (Leo de Bagnolas) invented an astronomical instrument, and his work upon this was translated into Latin by order of Clement VI, and was highly appreciated by Kepler. As translators of Arabic astronomical works the Jews made accessible the most valuable studies in the field. Ibn Ezra (qv) translated the *Canons of the Khwarezmi Tables* of Al-Muttani, Moses ibn

Tibbon the work on the Ptolemaic system by Jahir ben Aflah; Jacob Anatoli translated Ptolemy's *Almagest* and Averroës' compendium on this work. Profiat Tibbon was professor of astronomy at Montpellier. In the field which was then so nearly allied to astronomy — astrology — the interpretations of the Jews were much sought after, until they were forbidden by the rabbis as likely to lead to trouble.

In philosophy the Jews exercised an influence for which they have only received scant credit. Interested as they were mainly in reconciling Hebrew theology with philosophical speculation, their work fell directly into line with the aims of the early scholastics, and few of the leading medieval theologians failed to show a knowledge of Hebrew philosophical writings. While it is true that the Jews served mainly as intermediaries between Greek and Arabic philosophy on the one side and Christian theology on the other, without this mediation the development of scholasticism would have been retarded for many years until a direct knowledge of Aristotle would have been possible. The first Hebrew philosopher to exercise a marked influence on Christian philosophy was the Neoplatonist, Ibn Gabirol or Avicbron (1021-1058), possibly because he was not known for several centuries as a Jew. Ibn Gabirol's *Fons Vita*, translated into Latin at Toledo, c. 1150, served as a textbook of Neoplatonism, and was known by Duns Scotus, Albertus Magnus, Aquinas, William of Auvergne, and Alexander of Hales. The work was a matter in dispute between the Franciscans as represented by Duns Scotus and the Dominicans, represented by Albertus Magnus and Aquinas. Duns Scotus was a staunch upholder of Avicbron, and accepted his theory of the universality of matter, and the emanation of the divine will. The latter view was also accepted by Albertus Magnus, who devotes some space in the *De Causis et Processu Universitatis* to a consideration of Avicbron's views. But the most permanent and broadest influence was exercised by Maimonides (Moses ben Maimon, d. 1204) (qv) through the Aristotelian *Moreh Nebukim* (*Guide of the Perplexed*), translated into Latin within fifty years of his death. He is quoted freely by Albertus Magnus as Moyses Ægyptus, and his work as *Dux Neutorum*. The *Moreh Nebukim* is an attempt to reconcile revealed religion and rationalism or Aristotelianism. Albertus accepts Maimonides' theory of the creation, and, as against Aristotle, his arguments against the eternity of the world. Albert's *De Divinatione* is largely based on Maimonides, especially the distinction between visions, dreams, and prophecy. Where Albert differs from his authority, it is purely on doctrinal grounds. Thomas Aquinas is even more indebted to Maimonides, whose views he reproduces almost verbatim. He accepts the proofs of God's existence, the theory of the creation, and

the views on the eternity of the world, on God's omniscience, and on angels as intelligences or emanations of God. These instances will perhaps suffice in a brief account, but many others could be cited, — Isaac Israeli, for example, whom Albertus Magnus regarded as the greatest philosopher after Maimonides, David (possibly the same as Ibn Daud or Johannes Hispalensis), whose *De Causis* he quotes, Andrea (or Anatoli), who assisted Michael Scot, according to Roger Bacon, Levi ben Gerson, the astronomer and commentator on Averroes' Aristotelian commentaries, who exercised some influence on Pico del Mirandola. Many other Hebrew writers could probably be discovered on investigation, for it was a custom of medieval writers to quote without citing authorities.

The greatest contribution of the Jews to the development of medieval civilization was made by their activity as translators. The Jews by the conditions imposed on them were necessarily polyglot. They readily adopted the vernacular of the countries which afforded them a home. How catholic were their interests may be seen by a glance at Steinschneider's *Hebraische Übersetzungen des Mittelalters*. They entered every field of human knowledge which was accessible to them. Their translations into Hebrew were made from Latin, Arabic, Spanish, and other languages. With many the impulse was purely intellectual, others were professional translators in the pay of patrons, of whom Alfonso X, Frederick II, Charles of Anjou, Robert of Anjou, and Don Pedro are the most notable. There were two methods by which otherwise inaccessible works found their way into the hands of Christian scholars, — most usually the Jewish secretaries translated into the vernacular, and this was in turn translated into Latin, or else they themselves translated directly into Latin. One of the most famous centers for translation, especially from Arabic, was established by Raymond, Archbishop of Toledo (1130–1150), who was assisted by Gundisalvi. The chief translator was Johannes Hispalensis, or Avendeath (*ie* Ibn Daud), a Jewish convert, who translated mainly Arabic astrological and astronomical works and some philosophy. He compiled an *Epitome Totius Astrologia*, probably from Arabic. Among other works translated under Gundisalvi with the same assistance were Avicenna's *Physics*, in which another Jew, Solomon, collaborated, *De Anima*, *Metaphysics*, *De Celo et Mundo*, *De Ortu Scientiarum*; the *Khwarezmi* of Mohammed ben Musa; some works of Maschallah, an astronomer. Other interpreters were Abraham bar Chijja, the astronomer, who probably assisted Plato of Tivoli in the translation of his *Liber Embadorum*, a work on geometry, and possibly in translations of his astrological aphorisms, taken from the Arabic Chajjim (c. 1250) translated astrological works of Ibn Ezra into French, and assisted Hen-

ricus Bates and several others with Latin translations. In the service of Alfonso X, were Isaac ibn Sid (Rabbi Zag), who translated into Spanish several Arabic works on astronomical instruments and assisted in drawing up the Alfonsine Tables, Abraham Alfaguin, who translated part of the Koran; Judah b Astruc compiled a *Book of Sentences* in Catalanian dialect from Arabic, Hebrew, Greek, and Latin, a work intended for the education of the nobles; Judah b Moses translated Arabic astronomical works into Spanish, *e g* Costa b. Luka's *Globe*, and also a *Lapidarium* of Abolays. Charles of Anjou employed Moses Farachi or Faradi, translator of the medical work *Continens* of Razi, Pseudo-Galen, *De Medicinis expertis* from the Arabic of Hunain, and a medical dictionary of Abu Ali ibn Djazla (*Tacuyum aegritudinum et morborum corporis*), Moses of Palermo was taught Latin at the request of Charles for purposes of translation, and translated from Arabic Pseudo-Hippocrates' *Lub de Curatombus Infirmitatum Equorum*. Kalonymus b Kalonymus translated for Robert of Anjou, among other works mathematical and medical, many of Averroes' Aristotelian commentaries, *e g* *Topics*, *Sophisms*, *Analytics*, *Plants*. It would be impossible here to enumerate the number of independent translators and interpreters or to do more than indicate those who made Arabic works accessible through translations into Hebrew. Of these the most famous were the members of the family of Ibn Tibbon, who settled in the south of France about the middle of the twelfth century, Judah ibn Tibbon, the father of translators (1120–1190), Samuel (1150–1230), the translator of Maimonides, Moses (fl. 1240–1280), the translator of Averroes, Euclid, and Avicenna; Jacob b. Machir (Profatius Judæus, 1236–1304), the translator of Euclid, Averroes, Kosta ben Luka, and the *Almagest*. Jacob b. Abba Mari (Anatoli), a son-in-law of Samuel ibn Tibbon, was retained as translator by Emperor Frederick II, and collaborated with Michael Scot. Direct translations into Latin by Jewish scholars do not appear in any number until the fifteenth century, and among these may be mentioned the works of Elias Del Medigo (whose patron was Pico del Mirandola), Abraham de Balmes, Kalonymus ben Judah, Jacob Mantino, and Moses Alatino. From the end of this century on, the knowledge of Hebrew was sufficiently widespread for independent translations by Christian scholars.

**End of Medieval and Beginning of Modern Period** — In France the period of Jewish development came to a close with the persecutions which ushered in the thirteenth century. A decline had already begun to set in as a result of the disputes centering round Maimonides' philosophy and this was completed when the Talmud was burned at Paris in 1242, and the Jewish academies were closely watched. That some attempt was made to stem the de-

cline is indicated in a remarkable school statute of the thirteenth century, of which three different versions exist. A school organization is projected from top to bottom. A "petty school" was to be established under a superintendent of studies and teachers who were to have only ten pupils of selected ability under their charge. Books were to be used instead of the oral method, and translation into the vernacular was to be employed. Pupils should be encouraged to hear each other every night for mutual improvement. Weekly, monthly, and half yearly reviews were to be conducted by the teachers. In the capitals an academy or "great school" was to be maintained at public expense, to which the "separated" or oblates, i.e. the firstborn male children, were to proceed at the age of sixteen, the lecture system was to be employed here and tutors were to be appointed to conduct "quizzes." The whole course in both schools was to last fourteen years, beginning with the fifth or sixth year. While there is no evidence of such a system in practice in France, it is possible that it may have existed in England, for there appears to have been a small provincial school at Norwich and a great school (*Magna schola Judæorum*) in London. For this reason an English origin is assumed for the code (see J. Jacobs, *Jews of Angevin England*, p. 342).

The education of girls was not encouraged, for "education leads woman to error." She was to be educated for the home, and in any case the custom of early marriage precluded an education beyond a knowledge of the faith and ritual necessary for the home. Many women conducted businesses, while their husbands traveled for study; many encouraged learning by loan of books, and by helping poor students with board and lodging, some, however, did themselves attain considerable knowledge of religious traditions.

In Germany and Poland, however, the medieval system began to be stereotyped, and when the sixteenth century is reached the traditional Jewish educational institutions are firmly established. The center of Jewish learning, however, tended to move to Poland, where the German Jews gradually settled in large numbers. The institutions are (1) the *Heder* or *Talmud Torah*, giving instruction up to the age of fourteen or even sixteen, and (2) the *Yeshibah*, or rabbinical academy. The *Heder* (lit. "room") was a private school in which pupils paid tuition fees. The teacher (*Melammed*), not always a competent scholar, frequently taught in the one room of his house, in the midst of his family, while he continued his occupation or business, if he had one. Sometimes he would have the aid of an assistant (*Belfer* or *Behelfer*) who brought the pupils to and from school and taught the elements. Since the number of pupils was small and they varied in age, class instruction was generally impossible, much to the detriment of a con-

sistent curriculum. Among defects of the *Hedarim* in the seventeenth century are also mentioned the bitter competition between teachers, frequent changes of schools, dishonest practices to retain pupils, inadequate accommodations, etc. (Moses ben Ahron, 1635). An interesting statute was passed by the community at Nikolsburg in Moravia to remove these and other abuses (1676, revived 1726). A board of education was also established at Frankfort in 1662. The conditions of the *Heder* remained unchanged up to the present day, although some attempt is everywhere being made to improve them.

The *Talmud Torah* was originally a communal school for poor and orphan children. Toward the beginning of the sixteenth century Talmud Torah societies are found in most of the Jewish settlements in northern Europe, elsewhere communal boards of education were elected (e.g. Posen, Worms). In both cases schools were maintained by fees, by voluntary contributions, by a share of the contributions to synagogues, by collections made at circumcisions, marriages, and funerals, and by charity. In Cracow the Talmud Torah Society supervised both private and public schools, and weekly inspections of instruction were made (see Statutes 1551-1639). But although more rigorously supervised, the Talmud Torahs were not much superior to the *Hedarim*.

The curriculum in both types of schools was the same. From the age of two or three children were taught a few prayers and benedictions at home, and were introduced to the ceremonies. Entering school at the age of five, they were taught the alphabet, benedictions, the daily prayers (*Sidur*), the Pentateuch with translations into the vernacular, the rest of the Bible, exegesis (Rashi and other commentaries), and Talmud. Reading and writing in the vernacular, Hebrew grammar, and arithmetic were also taught in some schools. But the main emphasis was on religious instruction and practice. Toward the thirteenth year, the time of initiation, when the boys became legally members of the community (*Bar-mitzvah*), they were instructed in the laying of the Phylacteries (*Tefillin*). The method of instruction throughout was oral, and the traditional mnemonic devices and numerous reviews were employed. If a boy proved intellectually dull at fourteen, he was put to a trade, apprenticeship fees being paid by the community or societies for the poor. Those who had the ability entered the *Yeshibah*, the public academy under the charge of the rabbi.

Academies were to be found in all large towns, in Spain and the south of France they provided, as was shown above, a broad university education. In Germany and Poland all energy was devoted to rabbinical studies, and all profane or vernacular works were rigorously forbidden. The course of study consisted of the numerous commentaries and

exegetical writings on the Scriptures, *Mishnah*, and Talmud. The chief of these were the *Halakot* (an abridgment of the Talmud) by Isaac ben Jacob Alfasi (d. in Spain in the eleventh century), the *Turim* (a compilation of the codes, omitting those parts which were obsolete) of Jacob ben Asher (1340), and later the *Shulhan 'Aruk* (code on ritual and legal questions) of Joseph Caro (b. 1488). One part of the course was given to private study of *Gemara*, Rashi, and *Tossafot* (the glosses on the Talmud which were begun after Rashi). The students prepared questions on their readings, which were discussed by the Rabbi at the next meeting. Another part of the course was devoted to scholastic disputation to clarify any difficulties or contradictions in the codes. This method of disputation (*Pilpul*) tended to become an end in itself, and led to subtleties and quibbling, but it demanded a ready knowledge of the fundamental codes and commentaries. Learning was greatly esteemed, and the learned man was given the place of honor wherever he came. Boys of promise were eagerly sought in matrimony, and wealthy fathers willingly provided maintenance for learned sons-in-law.

**Modern Period** — These forms of education have in part continued up to the present time, more especially among the Russian and east European Jews. The emancipation of the Jews dates from the time of Moses Mendelssohn (1729-1786), who realized that their further progress depended upon their restoration to the normal conditions of social life. The vernacular which the secluded Jews spoke through centuries of isolation must yield to the national language of their German environment. In order to bring about this change, Mendelssohn translated the Bible into German, knowing that the acquisition of the language of their adopted country would be a right beginning toward the reformation, and that the Bible, always a household book among the Jews, would be the most effective means for the purpose. "Never was a people so serious and so passionate and so ideal in the pursuit of an education. Ten or twenty years sufficed to make a remarkable change. The dilettantes, who had preoccupied the schools and whose want of understanding of both their obligation and their opportunity had been in a large measure the cause of the decadence, disappeared, and schools arose in several places, patterned after the best models, such as the Philanthropin of Basedow (*qv*) in Dessau. Among these may be mentioned the Samson'sche Freischule at Wolfenbuttel, the Freischule of Berlin, the Philanthropin of Frankfort a. M., the Freischule in Seesen, and a large number of congregational schools all over the land. The Freischule of Berlin was organized on the plan of David Friedlander, the friend of Moses Mendelssohn, in 1778. When, in 1774, J. J. Basedow opened the Philanthropin, Mendels-

sohn urged that the Jews encourage the undertaking, and a brother of H. Wessely came to its support and enlisted a number of Jewish families for its patronage. But although the experiment failed, the Jews of Dessau, in the light of the experience and the interest in educational matters which it stirred, undertook to establish a school which should secure for the Jews the influences and the enlightenment so vividly desired by them. At first a school for poor Jewish children, it soon became a communal school receiving even non-Jewish children. This school was known as the Jewish Central and Free School (*Judische Haupt- und Freischule*), and later the Duke Francis School (*Herzogliche Franzschule*), its principal was David Fraenkel.

Noteworthy schools of this period are the school of Seesen, founded by the reformer Israel Jakobson in 1801, the school at Breslau established by Joel Loewe, a pupil of Moses Mendelssohn, in 1791, the Samson'sche Freischule at Wolfenbuttel, which graduated such eminent pupils as Leopold Zunz, the bibliographer, and J. M. Jost, the historian, and the Philanthropin at Frankfort a. M., which was established in 1805. Some of these schools are still in operation, though their method of instruction and their aims have been modified by the changed conditions and the modern conceptions of pedagogy.

In Austria, by the Edict of Tolerance issued by Emperor Joseph II (Oct. 29, 1781), Jews were permitted to establish schools of equal standing with those of Christians. It was the purpose of the "Toleration" to enable the Jews in the Austrian Empire to speak the prevailing language and to enter into the trades. The results of this liberal policy were not slow to appear. The Jewish educational institutions were organized by Heitz Homberg in 1818, who was supported in his labors for the uplift of the Jews by the wise and persistent policy of the government. The training of teachers was provided for at the very beginning of the movement for the reform of Jewish education. The Pedagogical Seminary at Cassel was established in 1809, and the one in Berlin, founded in 1840, was under the direction of Leopold Zunz. There are also seminaries at Munster and Hannover. The aim is to equip the teachers of the Jewish communal and congregational schools in a manner comporting with the modern requirements.

In England secular institutions were not established until the beginning of the nineteenth century. Talmud Torahs and religious schools probably existed earlier. In 1811 the Westminster Jews' Free School was established, followed in 1817 by the Jews' Free School in Whitechapel, now one of the largest elementary schools in the world. In the provinces, schools were not established until some years later, the Jews' Free School at Manchester and the Hebrew School in Liverpool were both

established in 1842. In 1851 the Jewish schools were allowed to share in the national grant to education. The subsequent history of the Jewish schools has been the same as that of other denominations voluntary or non-provided schools. (See ENGLAND, EDUCATION IN)

Jewish secular schools have not been numerous in the United States. Schools were early attached to synagogues and taught both religious and secular subjects. Hebrew schools were established in New York in 1808 by the Sheareth Israel. In Philadelphia a general Sunday school, not affiliated to any synagogue, was established in 1838, followed in the same year by one at Charleston, S. C., at Richmond, Va., in 1839, in New York in 1845 by the Emanuel Society. In 1864 a Hebrew Free School Association was established, in which the children were brought together irrespective of their synagogue affiliation and were taught by voluntary teachers. The rapid increase of immigration immediately raised a complicated problem, the extent of which has only recently been realized and which is only just being faced.

**The Present Problem** — The problem of purely Jewish education is becoming more and more difficult and complex in proportion as the facilities for secular education increase. In Russia and eastern Europe many of the types of schools referred to above, the Heder, the Talmud Torah, the Yeshibah, still play a significant and important part in the lives of the people, in Russia these schools also provide the secular education which is denied the Jews by the government authorities. But it is in the countries where freedom has been greatest that the decline of Jewish teaching has been most rapid. The Jewish religion has always been essentially a religion of the home, many of the ceremonials only have meaning as they are performed in the home, the welcoming of the Sabbath, the close of the Sabbath, the celebration of the festivals, are occasions for the inculcation in a concrete manner of Jewish tenets and Jewish beliefs in the minds of the young. The growing economic independence of children, and frequently the difference in outlook, due to difference in language and education, are tending to break down the home bonds and home life which have been at the root of Jewish life. This, however, is only one of many causes. On the side of the Jewish schools for the purely sectarian and religious education, little has been done to keep pace with the advance in educational thought and practice. The methods are still in the majority of instances the methods of the medieval period. Cramming and memory work without appeal to the understanding too often tend to arouse a rebellious spirit. On the material side, too, the schoolroom, especially the Heder, is too often an unsanitary room used for most other purposes of life beside teaching; the teacher,

however learned he may be, in most instances takes up his work as a *pis aller*. Class instruction is unknown in the Heder, and the boys take their lessons in turn for a few minutes at a time. The visiting Hebrew teacher (*Melammed*) is professionally of the same type as the master of a Heder, his presence is unwelcome, his methods as unmethodical, and his remuneration as miserable as of the Heder teacher. Of a higher type are the communal Talmud Torahs, which alone may hope to cope with the problem. They are housed in modern school buildings, they provide a consistent curriculum, and the beginnings are being made to train teachers for the work. Class work takes the place of individual and random tuition. Above all, instruction is given in the vernacular (English or German) and not in the Yiddish jargon. At present these schools have a struggling existence, since they are dependent to a large extent on voluntary contributions and fees. The curriculum generally includes elementary Hebrew, the Daily Prayers, the Pentateuch, the principles of Jewish faith and practice, and with more advanced students other parts of the Bible and simple commentaries. But even the Jewish parents who are anxious to educate their children in many cases have only the confirmation (at the age of thirteen) in view, after that time, when the boy is able to read his portion of the Law and to lay the Phylacteries, little further attention is paid to his education. As for the girls, their education is almost entirely neglected and rarely goes beyond ability to read and a knowledge of Jewish faith and practice. This problem is one of the most difficult which Jewish educators will have to face. Traditionally the home has always provided for the education of girls. The decay of the home, the early economic independence, the weak hold of the synagogue, the so-called attractions of the street contain in them the causes of many a tragedy. The girls, it must be recognized, have as great a claim on the attention of the Jewish school as the boys.

One other type of school may be referred to, the congregational school, modeled on the Sunday school, maintained in connection with a synagogue and meeting on Saturday afternoon or Sunday morning and sometimes one other period in the week. Here the program is less ambitious and is confined to a little Hebrew reading, Biblical and post-Biblical history, the Jewish creed, and some singing. But too often the teachers are voluntary workers, the school has not the support of the parents, discipline is weak, and the pupils attend at will and drop out early. There is a tendency, too, in the congregational schools, more particularly in those connected with the reformed synagogues, to abandon entirely the teaching and study of Hebrew, since services are in any case conducted in the vernacular. In these schools the curriculum consists of

Biblical history, singing, and some discussions of Jewish creed and principles.

Much thought is being given to the question of Jewish education both in England and America. In London the Jewish Religious Education Board (est. 1894) has for a long time certificated teachers for Sunday school work, and in New York several well-conducted Talmud Torahs have sprung up which meet the best requirements of secular schools in material conditions, and the Kehillah (Community) has established a Bureau of Education under an efficient director to consider the whole question of reform in the direction of efficiency. Statistics have been obtained of the number of unsanitary schools (Hedrim), of teachers, salaries, funds, etc., and conferences have been held for the improvement of the curriculum. One other tendency which will contribute in large measure to some reform is the strong national or racial movement, an offspring of the Zionist movement, which, without raising any question of loyalty to the adopted country, aims to arouse an interest in the cultural side of Jewish history and Jewish life. With these proposals there is frequently connected the adoption of the new method of teaching Hebrew by the direct method (*Ivrit be-Ivrit*), with which much successful work has already been done. The reformed curriculum will, therefore, have an emotional as well as an intellectual aim, it will stimulate an appreciation in the best that has been, and by dissipating ignorance will remove much of the besetting sin of contempt and scoffing. I. L. K. and L. G.

#### JOANNES DE GMUNDEN (c. 1380-1442)

— The first professor of mathematics, as a separate subject, in Austria. He is also known as Johann von Gmunden, and Johannes de Gamundia, and the names Wissbier, Nyden, and Schmdel, are also doubtfully assigned to him. He was born about 1380 at Gmunden on the Traunsee, Gemund in Lower Austria, or Gemund in Swabia. He died at Vienna, Feb. 23, 1442. He was educated at Vienna and was professor of mathematics there. He wrote a work on sexagesimal fractions (see FRACTIONS), *Tractatus de Minucius phisicis*. D. E. S.

**JOANNES DE MURIS** — A prominent writer on arithmetic, astronomy, and music. He was born in Normandy about 1310, and died after 1360. He is also known as Jean de Meurs (Murs, Muria). His *Arithmetica cōmunis* appeared in print in 1515. D. E. S.

**JOHN, ABBOT OF ST MARTIN'S.** — See BISCOP, BENEDICT

**JOHN B STETSON UNIVERSITY, DELAND, FLA** — A coeducational institution founded in 1887, the present name was adopted in 1889. The university maintains an academy, college of liberal arts, college of law, a business college, a normal school, a school of mechanics arts, a music school, and a school of fine arts. The entrance requirements are equivalent to sixteen units. Candidates for the college of law which offers a two years' course must satisfy the faculty with evidence of their qualifications. The degrees of A B, A M, B S, and LL B, are given on the completion of appropriate courses. The faculty consists of forty-seven members.

**JOHN OF DAMASCUS** — The founder of Greek scholasticism and the forerunner of the scholasticism of the West, was born in the latter part of the seventh century and died shortly before 574. He entered the cloister of St. Sabas at Jerusalem about 730, but even before that he had distinguished himself as a theological writer of ability. He spent two years of his noviciate at this monastery, and was ordained priest before 735 at Jerusalem. He spent the rest of his life almost entirely in his monastery of St. Sabas. His importance in the history of the Eastern Church rests upon his great dogmatic treatise in three parts, entitled by him the *Fountain of Knowledge*, his spirited defense of image worship, and his admirable hymns. Several of the latter are used in English translations by Neale, in the Eastern Church these compositions are of great liturgical importance. The importance of John in the history of education rests upon the use he makes of Greek philosophy in the first part of his *Fountain of Knowledge*. In this part, entitled Philosophical Chapters, later called *De Dialectica*, and intended to be introductory to theology, John establishes by practical use the principle that philosophy was to serve as the handmaid of theology or faith, a position which became a commonplace in Western theology and education in the Middle Ages, but was first stated and applied by John. With this conception of the relation of the two, he constructs a well-wrought-out methodology, based upon the categories of Aristotle and the universals of Porphyry's *Isagoge*. In this way the revived Aristotelianism, already strongly tinged with Platonism, became a part of the theology and theological training of the East. The *Fountain of Knowledge*, especially

the first or philosophical part and the third or the Exposition of the Orthodox Faith, continued for many centuries to be the most important and the authoritative summary of the philosophy and theology of the Greek Church, taking a place as a basis of teaching more authoritative than even the *Sentences* of Peter Lombard in the West, or the *Summa* of St. Thomas in the modern schools. But the influence of the work did not remain confined to the East. It was translated into Latin by Bernardino of Sienna in the fifth decade of the twelfth century, and was used by Peter Lombard in the compilation of the *Sentences*. From this translation it has been thought that Peter adopted his method of exposition, whereby quotations of the Fathers are arranged under each head. J. C. A. Jr

**JOHN OF SALISBURY** — A famous English scholar, teacher, diplomatist, historian, philosopher, and bishop of the twelfth century (1115-1180). Early in life he crossed over to France, where he studied for fifteen years under Abélard (*qv*) and other great teachers and secured the best scholarly training which was to be had. Returning to England, he became secretary to Archbishop Theobald, by whom his talent for practical affairs and remarkable scholarship were utilized in many ways. He was intrusted with many delicate and difficult undertakings both at home and abroad and exercised a quiet but powerful influence in the affairs of Church and State. Later on he was the trusted friend and adviser of Thomas à Becket, shared his misfortunes and was present at his tragic death. During the last four years of his life he was Bishop of Chartres.

He was an enthusiastic humanist and became the best classical scholar and the most elegant Latin writer of the Middle Ages. The range and readiness of his knowledge was unparalleled. He was more thoroughly familiar than any man of his time with the speculations of the ancient philosophers, was devoted to the Platonic tradition, and was the first to make the whole of Aristotle's *Organon* available to medieval readers. At the same time he was conversant with all the phases of the scholastic controversies and has given us accurate and critical accounts of contemporary philosophical

discussions His own philosophy is known as moderate realism He struck a middle course between the extremes of realism and nominalism, combining the most valuable elements of both. While he regarded dialectic as sterile in itself, he admitted its efficiency as an aid to other disciplines Reacting from the prevalent mysticism, he made a thorough examination of the psychological questions of the relative importance of sensation, perception, and understanding in arriving at concepts, and of the relations of faith, opinion, and knowledge His historical knowledge was wide and accurate, and his theology was based upon extensive patristic learning. His acute and active intellect never tired of hearing and weighing the views of the men of his time, and he has left us valuable estimates of their learning and philosophy His writings help us to understand the literary and scientific conditions of the twelfth century His great learning and indefatigable industry were applied largely to educational pursuits Not only was he one of the most cultured scholars of the century, but one of its greatest teachers, directing the investigations of a wide circle of learners He discusses frankly the educational conditions of his day and describes in detail the methods then in use He has left us in his *Metaphysics* one of the very few circumstantial accounts of medieval student life and educational procedure His writings form an invaluable storehouse of information as to the matter and method of scholastic education They cover a wide range of subjects His *Polycraticus* (*The Statesman's Book*) deals with the principles of government, philosophy, and learning and is the most perfect reflection remaining to us of the cultivated thought of the twelfth century His *Metaphysics*, in four books, is a defense of the method and use of logic and philosophy His *Letters*, some three hundred in number, shed valuable light upon the constitutional struggle then agitating England His *De Septem Septenis* is a treatise upon the Seven Liberal Arts as then understood and practiced His *Historia Pontificalis* and his *Lives of St Anselm* and *St Thomas à Becket* contain important historical materials, and possess great human interest W. R.

**JOHN SCOTUS ERIUGENA.**—See ERIUGENA.

**JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD**—Incorporated Aug 24, 1867, and opened Oct 3, 1876, has from its inception

been influential among American institutions in upholding high standards of scholarship and scientific research The university was founded by Johns Hopkins, who was born in Maryland, May 19, 1795, and died Dec 24, 1873, in Baltimore, in which city he had accumulated a fortune The first Board of Trustees was organized on June 13, 1870, and met on Feb 6, 1874 The Board is a self-perpetuating body of twelve members and the President *ex officio*; the trustees are elected for life The first president was Daniel Coit Gilman (*qv*); he was inaugurated on Feb 22, 1901, and held office during the first twenty-five years of the university, resigning on Feb 22, 1901 His successor was Ira Remsen, LL D, Ph D, professor of chemistry in the university, inaugurated on Feb 22, 1902 Upon the inauguration of President Remsen a suburban tract of 176 acres at Homewood was given as a future site by William Weyman, William Keyser, Francis M Jencks, Julian Le Roy White, and William H Buckler of Baltimore, and Samuel Keyser of New York Fifty acres of this property have been deeded to the city for a public park The site has been improved by the construction of a greenhouse and an athletic field Plans for new buildings have been drawn, after a competition among selected architects, and building operations have been begun

The institution maintains collegiate instruction for undergraduates Features emphasized in this work are the distinction between the discipline of college study and the freedom of advanced research, a modified elective system of studies (the "group system"; see COLLEGE, AMERICAN, under *Present Type of College Curricula*), and the influence upon undergraduates of distinguished professors and of the neighborhood of a body of graduate scholars conducting original investigations Admission depends upon the presentation of a certificate showing completion of courses in arithmetic, political geography, freehand drawing, and a science, preliminary to examinations in English, Latin, mathematics, history, and either Greek or French or German No certificates are accepted in place of examinations In 1907 the course was increased from three to four years, with an increase in enrollment The principal work of the university has lain in its graduate courses leading to the degree of Doctor of Philosophy, which may be gained in the departments of mathematics, physics, astronomy, chemistry, geology, zoology, botany, physiology, Greek, Latin, classical archæology, Sanskrit and comparative philology, Oriental languages, English, German, Romance languages, history, political economy, political science, and philosophy A graduate department of education is planned An important place in the university has always been occupied by the "fellows", twenty fellowships are awarded annually, each yielding \$500, but

not exempting the holder from tuition. Certain classes of individuals are also eligible for appointment as "fellows by courtesy." From its inception the university has offered, from time to time, systematic courses of public lectures. Since 1890 extension courses have been given for teachers and others in Baltimore; a number of these courses, which ordinarily do not carry credit for a degree, are offered in cooperation with Goucher College of Baltimore (*q v*). Admission is by examination or certificate. The medical school of Johns Hopkins University is one of the strongest in the United States. Its buildings, in another portion of the city from the other departments and adjoining the Johns Hopkins Hospital, include a central structure devoted chiefly to administration, two large private wards, a number of buildings containing separate wards, a large dispensary building, a surgical building and amphitheater, and a nurses' home. The Harriet Lane Home for Invalid Children, the Phipps Psychiatric Clinic, and the Phipps Dispensary for the Treatment of Tuberculosis are situated within the hospital grounds. The school has numbered among its professors Sir William Osler, now Regius Professor in Oxford University, Howard A. Kelly, a gynecologist, and William H. Welch, pathologist. The school is preeminent in medical research. Johns Hopkins University is one of the institutions originally accepted by the Carnegie Foundation for the Advancement of Teaching.

The buildings including those for the Medical School are valued at \$1,577,330.40, with equipment. The productive endowment is \$4,557,537.07. The State of Maryland appropriates \$25,000. The library has 137,000 volumes. The average salary of a professor is \$3184. There are (1910-1911) 197 members of the resident instructing staff, and 15 non-resident lecturers, 54 are full professors. The student enrollment was 781, of whom there were 156 graduate students, 348 medical students, 52 physicians attending special courses, and 188 undergraduates. C. G.

**JOHNSON, ELLEN CHENEY** (1819-1899). — Leader in the movement for reform schools for delinquent girls, was educated in the public schools and at the Francetown (N.H.) Academy. During the Civil War she engaged in the soldiers' relief work of the Sanitary Commission, and at its close engaged in prison reform work. She was a member of the Board

of Prison Commissioners of Massachusetts, and superintendent of the Massachusetts Reformatory for Women at Sherborn (near Framingham) from 1884 to 1899. She wrote many papers on reformatory education.

W. S. M.

See REFORMATORY EDUCATION.

**JOHNSON, SAMUEL** (1709-1784). — It would be strange if among the numerous interests of the great English writer, some characteristic utterances on education were not to be found. His own career as usher in the school at Market-Bosworth and as master of an academy where he only had three pupils, among them David Garrick, was not marked by success, nor does his *Scheme for the Classes of a Grammar School* display any originality. Strongly devoted to the humanities, he failed to recognize the value of other subjects. Hence the severity with which he criticizes Milton's *Tractate* and its emphasis on sciences and external nature. "The first requisite," he says, "is the religious and moral knowledge of right and wrong, the next is an acquaintance with the history of mankind, . . . we are perpetually moralists but we are geometers only by chance. Our intercourse with intellectual nature is necessary, our speculations upon matter are voluntary and at leisure . . . Those authors, therefore, are to be read at school, that supply most axioms of prudence, most principles of moral truth and most materials for conversation, and these purposes are best served by poets, orators, and historians." To the view that popular education would make people less industrious he replied, "when everybody learns to read and write, it is no longer a distinction." Of the public boarding schools he had a high opinion in general for "there is the collision of mind with mind, or the radiance of many minds pointing to one center." But there are exceptions, as in the case of dull or idle boys, where the private school is to be preferred. On the question of corporal punishment, Johnson has made several pronouncements, generally in its favor. He himself had been severely disciplined at school, but that apparently did not affect his judgment of it. "A child is afraid of being whipped, and gets his task, and there's an end on't, whereas by exciting emulation and comparisons of superiority, you lay the foundation of lasting mischief," and again, "Correction in itself is not cruel; children being not reasonable, can be governed only by fear." Of the power which he attributed to education the following is the best evidence. "I do not deny, sir, but there is some original difference in minds, but it is nothing in comparison of what is formed by education." Nowhere does Johnson devote himself to a general discussion of education, with the brief exception of the passage in the *Life of Milton*. His *obiter dicta*, however, are truly representative of the

## JOHNSON, SAMUEL, JR.

attitude of the cultured classes of the period to education

**JONES, HUGH** (1669-1760). — Educator, received his training in the universities of England. He was for sixty-five years a teacher and preacher in Virginia, and from 1702 to 1722 a professor in the College of William and Mary. He urged the introduction of history and civics into secondary school courses and recommended the establishment of special departments in the colleges for the training of the civil servants

of the colonies. He was author of a *History of Virginia*, and of several papers on educational topics. W. S. M.

**JORDANUS NEMORARIUS** (d. 1236) — The greatest mathematician of the thirteenth century, excepting Fibonacci (qv). He was born at Borgentreich, in the diocese of Paderborn, and died in 1236. He studied at Paris. He is also known as Jordanus de Saxonia. His arithmetic was based on the theory of numbers as set forth by Boethius. It was first printed in 1496, at Paris, and went through several editions. He also wrote a work *De Ponderibus* which was edited by Apianus and was published at Nurnberg in 1533. An *Algorithmus Demonstratus* is also attributed to him. D. E. S.

**JOUFFROY, THÉODORE-SIMON** (1796-1842) — French philosopher and psychologist, born at Pontets and died at Paris. Entered the École Normale in 1814, and in 1817 was made doctor of philosophy and *élève-répétiteur* in philosophy in the École, and was given the chair of philosophy in the Collège Bourbon, which he resigned in 1820. In 1822 the École Normale was closed, and Jouffroy began to give private courses in philosophy, and to write for several literary journals. When the École Normale was reopened in 1828, he was made *maître des conférences* in philosophy. From 1828 until his death he was in succession professor of ancient philosophy, adjunct professor of modern philosophy, and professor of philosophy in the Faculté des Lettres at Paris. From 1833 to 1838 he was professor of Greek and Latin philosophy in the Collège de France, and in 1838 became librarian of the University. Jouffroy was a pupil and associate of Cousin and of Royer-Collard. His spiritualistic rationalism exerted considerable influence on educational thought in France during the second quarter of the nineteenth century. His chief work was in translating and expounding the Scottish philosophy. His principal writings were translation of Dugald Stewart's *Moral Philosophy*, 1826, *Mélanges philosophiques*, 1823; *Cours de droit naturel*, 1835-1842, *Nouveaux mélanges philosophiques*, 1842, and *Cours d'esthétique*, 1843. **JOURNAL OF PEDAGOGY.** — See JOURNALISM, EDUCATIONAL.

**JOURNALISM, EDUCATION FOR.** — Professional education for journalism is of recent origin. Only within the last ten years in the United States has there been a decided movement in American colleges and universities toward the establishment and maintenance of courses in journalism or departments and

schools of journalism. Occasional lectures upon journalism had been given in various institutions, but no organized courses in journalism or in preparation for journalism had been offered. The state universities of the Middle West were the leaders in the training for the new profession.

In different colleges and universities different courses are given, and there are various forms of organization for the courses. At the University of Wisconsin courses are offered in the academic department associated with the work in English. In Kansas at the state University two years' work is given in reporting, and in news and editorial writing. The courses are grouped in the academic department. At the Kansas State Agricultural College, at the Iowa Agricultural College, and at the Wisconsin Agricultural College courses are given in agricultural journalism. These college courses are to prepare writers on farm papers for the presentation of the news of agriculture in clear, convincing, attractive style. At the University of Illinois, the University of Indiana, the University of Ohio, the University of Washington, the University of Pittsburg, and other institutions there are departments of journalism in which fundamental courses in the gathering and presentation of news are given. The University of California, the University of Oklahoma, the University of North Dakota, Marquette College, and other institutions give special work for students who plan to take up journalism as a profession. At the University of Missouri journalism is a separate professional school, coordinate with the schools of law, medicine, engineering, and education. It has a separate faculty and gives, upon completion of a three years' course, the degree of Bachelor of Science in Journalism. Sixty hours of college work, in addition to a four years' high school course, are required for entrance. In other universities the courses in journalism count towards the degree of Bachelor of Arts. The gift of the late Joseph Pulitzer, proprietor of the *New York World* and the *St. Louis Post-Dispatch*, of \$2,000,000 to Columbia University for the establishment of a School of Journalism in connection with that institution insures education for journalism at Columbia. At Cornell University, Yale University, the University of Pennsylvania, and the University of Virginia, and in several other institutions lectures on journalism, usually by men in the active practice of the profession, are given.

While all studies are regarded as helpful in education for journalism—so broad is the field of work of the journalist—the studies which he may take at the different colleges and universities are correlated so as to present the subjects which will be of the most immediate and practical service. Students in journalism are usually most interested in English and other languages, history, economics, sociology, psychology, political science, philosophy, and logic,

on the academic side. On the professional side, journalism courses in these institutions include courses in news gathering, reporting, news writing, newspaper making, newspaper administration, editorial writing, editorial direction, the history and principles of journalism, copy reading, illustration, the ethics of journalism, advertising and newspaper publishing, and newspaper jurisprudence. The last-named subject includes a consideration of the libel law in its relation to newspaper publication. The names of these courses given in education for journalism suggest their content.

The new movement in education for journalism has as its fundamental and distinctive feature the application of the laboratory method. The students in the present-day schools or departments of journalism are taught to produce newspapers by producing newspapers. In nearly every college or university where journalism is now seriously taught, the students of journalism issue, under faculty advice, supervision, or direction, a newspaper, usually a daily newspaper, the work on which, other than mechanical, the reporting, news writing, editorial writing and other work, is done by the journalism students. In some cases the entire publication, even the mechanical work—typesetting and press work—is by the students. As the hospital supplies bedside instruction to the student of medicine, the training school practice in teaching to the student of education, and the moot court a laboratory for the student of law, so the newspaper affords actual practice for the student of journalism. Some of these newspapers are not mere college journals, but are general newspapers, giving the news of the community in which they are published. They carry advertising in their columns and have regular subscription lists and the students make them profitable business enterprises. At this point the schools of journalism are not theoretical, but intensely practical.

More than one thousand students are now enrolled in courses in journalism in American universities. The number increases each school year.

Assuming the teaching of journalism or education in courses preparatory to journalism, the problem of organization for such education presents itself. Various conditions existing in various institutions made necessary various forms of organization. The organization, moreover, depends upon the extent of courses in journalism and upon the general purpose and content of such courses. An organization which is sufficient where only an occasional lecture on journalism is given, or where courses in journalism are offered in connection with an already existing department of instruction, is manifestly insufficient where more extended courses are offered and independently of any other department of instruction. The tendency is towards the sep-

arate grouping of journalism studies and to such organization of the professional school or department as will best bring about such separate grouping. This is obtained, in some degree at least, under practically any form of organization. It is obtained in the newer forms of organization by grouping specifically and formally the journalism students in a separate and distinct professional department or school in charge of a responsible faculty. In the organization of such faculty to the teachers selected from the College of Arts and Science or academic department, whose subjects are those prescribed or usually elected in preparation for journalism, are added the members of the so-called professional faculty, who are teachers who give courses in theoretical and practical journalism. The schools of law, medicine, engineering, and particularly the school of education, have afforded models for the organization of the school of journalism. This form of organization dignifies education for journalism, concentrates the attention of the students upon the subjects best adapted to their professional education and lends interest, emphasis, and strength to the courses thus offered. W W.

**JOURNALS AND JOURNALISM, EDUCATIONAL** — Specialized professional publications develop only with the growth of a profession. Hence educational journals of a professional type appeared only in the nineteenth century, and in most countries quite late in that century. Such professional journals were preceded by a type of publications, also properly called educational journals, which aimed to create popular sentiment in favor of public education. These in turn were preceded by a type of publications which were designed to improve the general intellectual condition of the people. Among these were *The Tatler* (1709) and *The Spectator* (1711) in England, and the *Moralische Wochenschriften* (1713) in Germany. These were counterparts of numerous book publications, such as *Defoc*, *Family Instructor*. The development of professional publications follows closely that of develop-

ment of educational associations (*qv*). (See also EDUCATIONAL JOURNALISM.)

The following article gives, first, the more important of the second type of magazines in England, the United States, and Germany, and second, a selected list of contemporary educational publications of various types in a large number of countries where the educational interest is great. In this connection see also the bibliographies in connection with the articles on the educational systems of the various countries, and also the article on OFFICIAL PUBLICATIONS ON EDUCATION.

**England** — Just as the study of education and the growth of a teaching profession are of recent origin, so the journals devoted to the interests of the subject and the profession made only a fitful progress up to the last quarter of the nineteenth century, from which period the best of the modern educational journals date. Although, as will be seen from the following article, which is not exhaustive, the number of such journals is large, few continued for more than about five years. But much valuable matter dealing with administration found, as it still finds, its way into the general magazines, periodicals, and newspapers, with which, however, no attempt will be made to deal in this article. Of the early magazines many were devoted to special causes or were associated with special societies. Probably the earliest educational journal in England was the *Guardian of Education* conducted by Mrs. Trimmer of Lancasterian fame as "a periodical work consisting of a practical essay on Christian education, founded immediately on the Scriptures and the sacred offices of the Church of England, memoirs of modern philosophers and extracts from their writings, extracts from sermons and other books relating to religious education, and a copious examination of modern systems of education, children's books and books for young persons." It appeared in 1802, and eight or nine numbers were issued each year, dealing with education from the religious and moral point of view. This magazine existed for four years. It is significant that more magazines were devoted to Sunday school work than to any other branch of education. The nature of the magazines which follow needs no further description. *The Sunday School Teachers' Magazine and Journal of Education* (1830-1867), the *Directory of Sunday School Teachers* (1831), the *Teachers' Offering and Sunday School Monthly* (1840-1862, 1863-1864), *The Teachers' Manual, a Repository of Practical Suggestions and Biblical Illustrations* (1840-1845), *The Sunday Scholar* (1843-1844), *The Sunday School Directory of Scripture Instruction together with the Psalms and Lessons* (1844-1846), *The Teachers' Monthly Magazine* published by the Church of England Sunday School Institute (1851-1854), and continued in 1857-1864 as the *Church of England Sunday School Monthly Magazine for*

*Teachers*, and in 1865 as the *New Monthly Magazine for Church of England School Teachers* (1865-1867); and many others. A periodical of a general educational character was the *Educational Magazine and Journal of Christian Philanthropy and of Public Utility* (1835-1836), continued as the *Educational Magazine and Journal of Scholastic Literature* (1839-1841), which during its last year was edited by F. D. Maurice (*q v*). The *English Journal of Education* was "specially designed as a medium of correspondence among parochial clergymen and all promoters of sound education, parents, sponsors, schoolmasters, Sunday school teachers, etc." (1843); with it were incorporated the *Educational Expositor* (f 1853), the *Educational Guardian* (f 1859), and the *Museum* (f 1861) in 1863 or 1864. It dealt also with elementary education and general educational questions, foreign educational systems, etc., although the belief was declared in the opening pages "that the principles of our education need not be imported from any other shore." The *Home and Colonial School Society Quarterly Educational Magazine* (1848) was the record of the society of that name (*q v*), and had as its object the "Christian education of the people." The same society issued in 1859 the *Home and Colonial School Society Educational Paper*, intended to help teachers in elementary schools by means of papers and the theory and practice of education. In 1831 the Society for the Diffusion of Useful Knowledge, of which Lord Brougham (*q v*) was chairman, issued the *Quarterly Journal of Education*, which attempted to record the progress of education in various countries and to communicate interesting developments and secure unity to education in the British Isles. This journal lasted until 1836. The British and Foreign School Society made known its objects through its organ, the *Educational Record* (1848), a continuation of the *Quarterly Extract* (1827), which also published notes as to the central administration of elementary education and papers on method, and still continues to appear. The *Educator, or Home, the School and the Teacher*, was established in 1854 as the organ of the Congregational Board of Education. The agitation for the centralization of education was responsible for several periodicals. The *Advocate of National Instruction* appeared in 1853 "for promoting the establishment of a general system of schools for secular instruction, supported by local rates and under local management" (1853-1854). The organ of the National Education League was the *National Education League Monthly Paper* (1869-1877), which discussed elementary education from the standpoint of undenominationalism; while a contemporary periodical in the interests of voluntary schools was the *National Society's Monthly Paper* (1847), which in 1876 became the *School Guardian*, a weekly educational newspaper and review.

Magazines of purely professional interest made their appearance throughout the century, but were all short-lived. The *National School Magazine* (1824), though intended for boys and girls, was a strong advocate of the national school. The *Educational Review and Magazine* (1826) only existed one year in the interests of higher classes of society. The *Schoolmaster* (1829) indicates its scope in its subtitle, "a weekly essay, the object of which is to point out the errors and defects of the present systems of education and modes of managing children and to propose better." The *Quarterly Journal of Education* has already been referred to as having appeared in 1831. The *Scholastic Journal and Magazine of Education* was issued for one year (1840). In 1844 appeared for the one year the *British Annals of Education, being the Scholastic Review* "of educational, philosophical, scientific, artistical, and general intelligence." In 1847 was formed what has proved to be the longest lived educational journal in England, the *Educational Times*, the official organ of the College of Preceptors (*q v*), which records current events and discusses educational questions, a feature of this journal has for a long time been the number of pages each month devoted to mathematical problems. The practical work of teachers in elementary schools was treated in the *Papers for the Schoolmaster* (1851-1853). The *Educational Expositor*, "specially designed for schoolmasters and schoolmistresses, mothers of families, and all interested in education" (1853), included principles and methods of teaching, biography of eminent teachers and educators, translations from foreign educational works and reviews, it was incorporated with the *English Journal of Education*. The three branches of education, elementary, secondary, and university, were covered in the *Literary or Educational Gazette*, "a weekly journal of Education, Literature, and Science" (1857). The *Educational Guardian* was edited and conducted by schoolmasters in the interests of the elementary school teacher mainly (1860-1863) when it was incorporated with the *English Journal of Education*. The pupil teacher system, by which young apprenticed teachers were practically thrown on their own resources to prepare themselves academically for the profession, led to the publication of several journals in their interests, of these may be mentioned *The School and the Teacher*, "for the use of schoolmasters, schoolmistresses, and pupil teachers in elementary schools, conducted by Church Schoolmasters" (1854); the *Pupil Teacher*, a monthly journal of practical education and educational literature (1857), the *Teachers' Assistant and Pupil Teachers' Guide* (1876-1880), incorporated with *The Students' Magazine*, a monthly journal of assistance for private and class students in literature, science, and art; *The Teachers' Magazine*, being a monthly miscellany of

hints and helps to elementary teachers (1880)

The *Museum*, which was issued in 1861, was "a quarterly magazine of Education, Literature, and Science," and aimed to give an accurate record of educational events, to discuss current educational questions, and to combine with this the element of general literature. It included among its contributors Sir Joshua Fitch, S S Laurie, and J S Blackie. In 1865 it was issued monthly under the title *Museum and English Journal of Education*, having incorporated the *English Journal of Education* mentioned above. The *Academia*, scholastic, educational, and literary record (1868), was a journal which discussed both elementary and secondary questions, but was probably intended for secondary teachers. In 1869 appeared the *Educational Reporter*, "a new monthly journal reflecting the opinions and advocating the interests of the scholastic profession," which up to 1874 dealt with elementary and science teaching, and after that date as the *Educational Reporter and Teachers' Review* gave a large share of attention to questions of secondary education.

In 1870 the *School Government Chronicle*, now the *School Government Chronicle and Education Authorities Gazette*, made its appearance. This journal is the best organ on the administration of education, its reports and comments covering the proceedings of Parliament, the Board of Education, the Local Government Board, the Home Office, and the local education authorities. All parts of the educational system are dealt with. For a long time the journal stood for the principles of unity in the educational profession and administration, which was more or less achieved in 1899 and 1902. The *Educational Review*, which has as its subtitle "embracing topics of interest in general literature and science," appeared from January to July of 1871, and contained papers dealing with all grades of education. The National Union of Elementary Teachers began in 1872 the issue of its official organ, which has continued to appear weekly to the present day as *The Schoolmaster*, dealing not only with current news about elementary school teachers, but questions brought up in Parliament and educational committees particularly affecting elementary education. The *Journal of the Women's Education Union* (1873), edited by Miss Shurreff and G C T Bartley, was, as the name indicates, the organ of the society which aimed at the improvement of education for all classes of women.

In 1879 the *Journal of Education*, which is at present one of the leading educational periodicals in England, was issued for the first time under its present title. Its history goes back to 1870, when the *Quarterly Journal of Education and Scholastic Advertiser* appeared, the title was changed in 1875 to the *Monthly Journal of Education*, and in the following year

to the *Journal of Education* with which are incorporated the *Educational Reporter* and *Scholastic Advertiser*. In 1879 there was also incorporated in the present magazine the *Scholastic Register*, which dated from 1869. The *Journal of Education* is the best record of English educational thought and practice. Among the contributors may be found the names of most of the leaders in the recent educational development of England. The journal is the official organ of the Teachers' Guild (*q.v.*) since 1884, and is also employed as the medium of communication of the Association of Teachers in the Secondary Schools of Scotland and the Incorporated Association of Assistant Masters. While the articles deal with all phases of education at home and abroad, secondary education receives particular attention. Another feature is the Translation Prize which has been offered monthly since 1879. In 1881 was started the *Practical Teacher*, which still continues as a monthly devoted largely, but by no means altogether, to the interests of infant and elementary school teachers. Child study, geography, and science also form features of the journal. *School*, a medium for the ventilation of all matters of educational interest, was issued for four years (1886-1890). In 1899 another of the current leading periodicals was established, the *School World*, a monthly illustrated magazine of educational work and progress, devoted mainly to questions of secondary education and the practical work of the classroom. Important contributions have appeared on the teaching of science in all its branches. Notes are given on educational progress throughout Great Britain and Ireland. Recently the scope of the articles has been extended, becoming more general in character than formerly. *School*, a monthly record of educational thought and progress, appeared for five years (1904-1909), and dealt with topics of general interest in educational theory, practice, and administration.

The formation of numerous associations within the last few years (see EDUCATIONAL ASSOCIATIONS), devoted to special subjects, has led to an increase in the number of special-subject periodicals, of which the following may be mentioned: *Classical Review* (monthly), connected with the Classical Association of England and Wales, and of Scotland, and of the Oxford Philological Society, and the *Classical Quarterly*; *Modern Language Teaching*, the organ of the Modern Language Association, the *Modern Language Review*, the *Mathematical Gazette*, the organ of the Mathematical Association; *Child Study* (formerly the *Paedologist*, 1899), of the Child Study Society; *Child Life* (1899), of the Froebel Society; and several others. A number of periodicals serve as the organs of general educational associations, of which some have already been referred to; others are the *A M A.*, of the Assistant Masters' Association; the *Teachers' Guild*

*Quarterly*; the *Preparatory Schools' Review* (1895), of the Association of Preparatory Schools, the *Parents' Review* (1890), of the Parents' National Education Union, *Secondary Education* (1896), of the Private Schools Association, Incorporated, the *Highway*, of the Workers' Educational Association, *Training College Record and Journal of Experimental Pedagogy*, of the Training College Association, and several local publications. The most recent publication is *The Child*, "a monthly journal devoted to child welfare", it is according to announcements, "a medico-sociological and educational journal dealing with all questions relating to infancy, childhood, and youth." The first number appeared in October, 1910.

A E T and I L K

**United States.** — The first educational journal published in the United States was *The Academician* (1818-1820). It was a semi-weekly of sixteen octavo pages, and was edited by Albert and John W. Pickett and published by the Incorporated Society of Teachers of New York. The first number appeared on the 7th of February, 1818, and included essays on the best modes of education, notices of literary and philosophical institutions, and observations on moral and physical science. The labors of Pestalozzi and Joseph Lancaster, and the reforms which they advocated, were leading features of the journal during its two years' existence. *The American Journal of Education* (1826-1830) was a monthly of sixty-four octavo pages edited by William Russell (*qv*), and was published by Tait, Green, and Co., of Boston. The first number (January, 1826) contains a prospectus of eight pages by the editor, in which he observes that "the spirit of inquiry, which has of late extended to everything connected with human improvement, has been directed with peculiar earnestness to the subject of education." Science and literature, he points out, have their respective publications, but education, a subject of the highest practical importance, has hitherto not had a proper vehicle of information. The field to be occupied by the new journal was to include (1) record of facts regarding the past and present state of education in the United States and foreign countries, (2) enlarged and liberal views of education, with means of improvement in the science of instruction, (3) physical education, (4) female education, a topic which the editor deems "unspeakably important", (5) moral training; and (6) early and elementary education. The editorial statement was followed by original articles on systems of infant schools, progress of physical education, course of study in the New York High School, and the Boston Monitorial School, the latter by William B. Fowle (*qv*). Twelve pages of reviews and ten pages of intelligence completed the first number. Subsequent numbers contained articles on infant schools, the lyceum movement,

female education, monitorial schools, the educational value of the study of Latin and Greek, progress of education in the United States and Europe. The articles as a rule were not signed, but so far as there are signatures and initials, the contributors included Samuel R. Hall, A. Bronson Alcott, Thomas H. Gallaudet, William B. Fowle, Wilbur Fisk, William C. Woodbridge, James C. Carter, Walter R. Johnson, Cornelius C. Felton, and Josiah Holbrook (*qqv*). Among foreign educational writers whose articles were translated and republished were Pestalozzi, Jacotot, Maria Edgeworth, Jean Paul Richter, George Combe, and Elizabeth Harrison. The foreign correspondence included letters from Louvain on Jacotot's system of instruction in languages, Fellenberg's scheme of agricultural and industrial education at Hofwyl, and nine of Pestalozzi's letters to James Pierrepont Greaves (*qv*), on early education. William C. Woodbridge (*qv*) succeeded Mr. Russell as editor of the journal in January, 1829, and in June, 1830, it was merged into the *American Annals of Education* (1830-1839). The *Annals* continued the form and general character of the *Journal*. Mr. Woodbridge declared in his introductory editorial that it was his purpose to make the *Annals* subservient to the best interests of educational progress, and to draw from other countries the fruits of experience and observation in matters of institutions and methods of instruction. The first volume contained letters from Hofwyl on Fellenberg's system of education, accounts of educational legislation in New York, New Jersey, and Kentucky, and a notable series of articles on teachers' seminars by Thomas H. Gallaudet (*qv*). Among important articles in subsequent volumes of the *Annals* were the study of modern languages, school discipline, the language of infancy, manual labor schools, study of American history, ventilation of schoolhouses, use of the Bible in the public school, the study of physiology, music as a branch of education, moral and religious instruction, female education, truancy, education and crime, the use of pictures in schoolbooks, education of the American Indian, infant schools, letters from Hofwyl (twenty-two in all), articles on Harvard, Yale, Columbia, Princeton, Dartmouth, and West Point. The contributors included Walter R. Johnson, Catherine E. Beecher, Thomas H. Gallaudet, Samuel R. Hall, Goolde Brown, John Guseom, Lydia H. Sigourney, George Ticknor, Thomas S. Grimké, Jacob Abbott, William A. Alcott, Henry R. Schoolcraft, James G. Carter, William B. Fowle, Warren Burton, Theodore Dwight, Samuel G. Howe, and Horace Mann (*qqv*). Mr. Woodbridge was the editor of the *Annals* from 1830 to 1836, William A. Alcott during 1837, and M. G. Hubbard from 1838 to 1839. It was published in Boston, first by Carter and Hendee and later by Ticknor and Allen. Contemporaneous with the *Annals* was *The Com-*

*mon School Assistant* (1836-1840), a monthly journal edited at Albany by J Orville Taylor (*q.v.*). As its name indicates, it was directly interested in the common school movement and the review of elementary school textbooks. Its contributors included James Wadsworth, Gideon Hawley, and John C Spencer. Another New York state journal was *The District School* (1840-1852), edited by Francis Dwight (*q.v.*), and including among its contributors Horace Mann, Henry Barnard, W F Phelps, and Samuel S Randall (*qq v*). Still another New York journal was the *Teachers' Advocate* (1845-1852) which was edited by Joseph McKeen and to which Salem Town, E North, Emma Willard, Catherine E Beecher, William A. Alcott, and Chester Dewey contributed articles. This was followed by the *New York Teacher* (1852-1865) edited by Thomas Weston Valentine (*q v*). In New England the logical successors of the *American Annals of Education* were the *Common School Journal* (1838-1848), edited by Horace Mann (*q v*), and the *Connecticut Common School Journal* (1838-1842), edited by Henry Barnard (*q v*). Of most significance, however, was Barnard's *American Journal of Education* (1855-1881). This comprehensive work -- thirty-one octavo volumes of more than eight hundred pages each -- is a veritable encyclopedia of education. At a meeting of the American Association for the Advancement of Education (*q v*) held at Washington in 1854, Henry Barnard submitted a plan for a new quarterly journal of education which should include "accounts of systems, institutions, and methods of education, as well as current educational thought." The plan was approved by a committee appointed to consider the scheme, but as the necessary funds were not available, Barnard in the next year undertook the journal on his own responsibility. The first volume included accounts of the meetings of the American Association for the Advancement of Education (*q v*), Frederic D. Huntington's *Unconscious Tuition*, since become an educational classic, accounts, with statistics, of educational movements in England, France, Germany, Holland, and Russia, and the American states; sketches of the Lawrence Scientific School at Cambridge, the Peabody Institute at Danvers, the American Institution for the Deaf at Hartford, and the Perkins Institution for the Blind at Boston, with steel portraits of the founders of these institutions; papers on methods of teaching Latin, Greek, mathematics, and the physical sciences; education among the Hebrews and the Cherokee Indians, educational biographies of Ezekiel Cheever (*q v*) and Thomas H Gallaudet (*q v*); besides articles on school discipline, the education of women, improvements practicable in American colleges, and the prevention of crime among children. The *Westminster Review* said of it: "The first volume of the *American Journal of Education* we received with unmingled pleasure,

save in the regret that England has as yet nothing in the same field worthy of comparison with it." Practically all important educational writings, from Plato's *Republic* to Herbert Spencer's *Education*, were published in Barnard's *Journal*. He included accounts of all the great school systems of the world; histories of the systems of the different states of the American Union; sketches of the great educational reformers of the world, as well as of American educational leaders. Normal schools, institutes of technology, colleges and universities, educational associations, institutions for defective, dependent, and delinquent children, libraries, kindergartens, and practically every other subject relating to education, found exhaustive treatment in this monumental work; and all the American and foreign educational writers of the first three quarters of the nineteenth century are represented in its columns. In the publication of his *Journal* Barnard spent a private fortune of more than forty thousand dollars. To prevent the plates from going into the melting pot for type metal, the Henry Barnard Publishing Company, with William T Harris as president and C W Bardeen as secretary, was organized in 1891. The *Journal* is now published and sold by Mr Bardeen as a work of reference. The *College Courier* (1869-1874), edited by Chester C Chatfield, was devoted to the interests of secondary and collegiate education, and *The Academy* (1886-1892), edited by George A Bacon, was devoted to secondary education. Among the current American educational journals are the *Journal of Education* (1875), *School Bulletin* (1874), *School Journal* (1870), *Popular Educator* (1884), *Education* (1880), *Journal of Pedagogy* (1887), *Educational Review* (1891), *Pedagogical Seminary* (1891), *School Review* (1893), and *Elementary School Teacher* (1900). In many of the states of the Union there are journals which meet the local needs of particular geographic sections of the country.

W S. M.

**Germany** -- The history of educational journals in Germany goes back to the early part of the eighteenth century. Their forerunners were the "moral weeklies" (*Moralische Wochenschriften*), the earliest of which appeared in Hamburg in 1713, and which were modeled after Steele's *Tatler* (1709) and Addison's *Spectator* (1711). Many other cities followed, such as Leipzig, Zurich, Berlin, Gottingen, Jena, Magdeburg, Konigsberg, Danzig, Frankfort, etc. The most influential of these papers were the *Discourse der Mahlern*, published by the Swiss poets Bodmer and Breitinger in Zurich (1721), *Der Patriot* (Hamburg, 1724), and Gottsched's publication, *Die vernunftigen Tadelrinnen* (*Reasonable Female Critics*) (Halle and Leipzig, 1725). These and their numerous imitators devoted much attention to the reform of education. Many of the pedagogical ideas which later on were advocated by Rousseau and

Basedow find an earlier expression in these old weeklies. Through their influence on the educated classes, they prepared the soil for the spread of that enthusiasm for education which characterizes the second half of the eighteenth century.

Gradually the pedagogic interest in many of these weeklies predominated over the literary and social, and purely pedagogic journals also began to be published. Among the earliest are *Der getreue Hofmeister* (*The Faithful Tutor*), Frankfort and Leipzig, 1725, *Vierteljahrliche Unterhandlungen mit Menschenfreunden über Erziehung* (*Quarterly Discussion with Philanthropists on Education*), published by Basedow in Bremen, 1768-1769, *Der Kinderfreund*, by C. T. Weisse, Leipzig, 1776, 24 vols., *Pädagogische Ungelichungen*, by Campe and Basedow, Dessau, 1777, *Das Schweizerblatt*, by Pestalozzi (1782), *Der Bote aus Thüringen*, by Salzmann (Sehneppenthal, 1788). In the early part of the nineteenth century the most important pedagogical journals were Zerrenner's *Deutscher Schulfreund* (Magdeburg, 1791-1823), Stephani's *Der bayerische Schulfreund* (Erlangen, 1811-1832), and Gutsmuths's *Bibliothek für Pädagogik, Schulwesen und die gesammte pädagogische Literatur* (Gotha, 1800-1819).

With the greater attention paid to the preparation of the teacher and with the rise of the teachers' profession, the number of pedagogic journals increased, so that, at the beginning of the second quarter of the century, there were about twenty published in the different provinces of Germany. Prominent among these was Diesterweg's (*qv*) journal, *Rheinische Blätter für Erziehung und Unterricht* (1827-1902), and the *Allgemeine Schulzeitung*, which was published by Dilthey and Zimmermann in Darmstadt (1824-1881). The present output of the educational press in Germany is far in advance of that of any other country, both in the number of periodicals and the degree of specialization which has been reached. Not only every province, but almost every district, has its own educational paper, while, at the same time, a considerable number of papers circulate all over the country. Many of them appear weekly, or even twice a week, and one, the *Preussische Lehrerzeitung*, is a daily publication. The local papers are generally controlled by the teachers' associations, which are found in every part of Germany. Every kind of school, every subject of school study, as well as every important educational movement, has its own publication. Thus there are not only separate journals for the kindergarten, the Volksschule, the Bürgerschule, the Gymnasium, the Realschule, the University, as well as for teachers' seminaries, trade schools, commercial schools, continuation schools, etc., but, in addition to these, special periodicals for the study of methods in religious instruction, the mother tongue, modern languages, classical languages, geography, history, mathematics, biology,

physics, and chemistry, drawing, manual training, physical education, etc. The fight for the reform of secondary schools was largely carried on in the *Zeitschrift für die Reform der höheren Schulen*, founded by Fr. Lange (Berlin, 1889), while *Das humanistische Gymnasium*, published (since 1890) by Jäger and Uhlig, represents the point of view of orthodox classicism. The success of the reform method in the teaching of modern languages was greatly aided by *Die neueren Sprachen*, founded in 1893 by Vietor in Marburg. In like manner the teachers interested in school hygiene, in female education, in the playground movement, in Herbartian pedagogy, and other movements, have each their own separate periodicals. There are also a number of educational periodicals especially devoted to the interests of Catholic schools.

The official publications of the different states, such as the *Zentralblatt für die gesammte Unterrichtsverwaltung in Preussen*, which has been published since 1859 by the Prussian Ministry of Education, furnish a periodical record of changes in laws and regulations affecting the schools. Of great importance also are the various *Jahrbücher* or annuals; the most important of these is the *Pädagogischer Jahresbericht*, founded by Naeke in 1845, and the *Jahresberichte über das höhere Schulwesen*, published since 1887 by Rethwisch in Berlin, the first devoted chiefly to elementary schools and the second to higher schools. Of the highest rank, both by the weight of its articles and the liberal spirit of its discussions, is the *Monatsschrift für höhere Schulen*, whose two editors are members of the Prussian Ministry of Education, this journal, whose publication was begun in 1902, immediately after the great Educational Conference of 1900, undertakes to further the reforms in secondary school methods, initiated by the Conference. Similar in the spirit of broad tolerance are the *Lehrproben und Lehrgänge* (*Model Lessons and Courses of Instruction*) which have appeared since 1885, in quarterly installments (Halle, Waisenhaus), a journal that furnishes a valuable record of improvement in the teaching methods of secondary school subjects. Akin to these journals in their great educational significance are the official published records of the *Direktorenkonferenzen* in the various provinces of Prussia since 1879; at each of these conferences several important educational questions form the basis of prolonged discussions, each question being introduced by an expert referee previously designated for the task, a typical summary of the conclusions reached in these conferences published in Killmann, *Die Direktoren-Versammlungen des Königreichs Preussen von 1890-1900*. (Weidmann, Berlin.) *Frauenbildung*, edited by Dr. Wychgram since 1902, is the organ for the school activities of women in the different types of schools. In addition to these there are a number of statistical yearbooks and

calendars, among which *Minerva*, a calendar for universities, and *Mushacke's German School Calendar* may be mentioned F. M.

**France.**—Magazines dealing exclusively with educational questions did not appear in France until the organization of public education by the Convention and by Napoleon. In the eighteenth century such topics were not treated outside of special works, except in the *Mercure de France*, the *Encyclopédie* of Diderot (*q.v.*), the *Journal de Trévoux*, etc. It was during the decades of the revolutionary period that they found a place. At that time, 1811, Guizot founded the *Annales de l'Éducation*, soon after (1816) appeared the *Journal d'Éducation*, published by a society organized in Paris for the improvement of elementary education. This society, which is still active in the Rue du Fouarre in Paris, was the ancestor and prototype of the *sociétés philomatiques*, *associations philotechniques*, *cours d'adultes*, etc., so widespread in these days.

At present the educational journals may be divided into five classes (1) Kindergarten and infant school journals for the information of teachers in these schools, *e.g.* *L'Éducation Infantine*. To these may be added the recreational journals which are intended for children on the model of the *Magazin Pittoresque*, established in 1833, and which have increased since 1880, *e.g.* *Mon Journal* (1881), *St Nicholas* (1880), etc. (2) Journals for teachers in elementary schools. These are the most numerous. They contain official documents, subjects for pupils' home work, information for use in classroom, educational suggestions, etc. The chief of these are the *Manuel Général de l'Instruction Primaire*, established in 1832, weekly in 1850, monthly in 1858, and again weekly in 1864, and now conducted with the *Dictionnaire de Pédagogie* under the direction of M. F. Buisson, the *Revue de l'Enseignement Primaire et Primaire Supérieur*, a weekly giving besides educational articles others referring to professional, social, and associational questions. The *Revue Pédagogique*, under the direction of a committee of administrators, educationists, and members of the Ministry of Public Instruction, dealing with questions of primary, secondary, and higher education. (3) Journals for secondary education are the fewest in number. One of the earliest was *L'Université*, devoted to questions of public instruction and secondary education (1883); the *Revue de l'Enseignement Secondaire* (1884), which under the direction of M. Jules Gautier has cooperated in the majority of the reforms in secondary education; *Revue Universitaire de l'Enseignement Secondaire* (1891), changed to *Revue Universitaire* in 1892, *L'Enseignement Secondaire des Jeunes Filles*, etc. (4) Journals for higher education; in 1863 was established the *Revue des Cours Littéraires de la France et de l'Étranger*, and the *Revue des Cours Scientifiques*, etc., which in 1870 became the

*Revue Bleu* and the *Revue Scientifique*, in 1878 M. Boutmy founded the *Société de l'Enseignement Supérieur* to examine all questions relative to higher education, and to collect all documents, this society has set in motion most of the reforms made in higher education, and has as its organ the *Revue Internationale de l'Enseignement* now under the direction of M. F. Picavet. Since 1892 there has appeared a *Revue Hebdomadaire des Cours et Conférences* in the Sorbonne, etc., originally undertaken by a group of students in the Sorbonne. Nearly all the special studies of the universities have each their own reviews. (5) Journals for general educational questions, with discussions on school hygiene, physical and moral education. These are at present few in number. There may be mentioned *L'Éducation Moderne*, established in 1906 by J. Philippe and G. Paul-Boncour, and now under the direction of G. Compayré, *L'Éducation* established in 1909 by G. Bertier. J. P.

The following is a list of current educational periodical, with the frequency of their issue (a., annual, q., quarterly, m., monthly, f., fortnightly, w., weekly, d., daily, irreg., irregular) —

In addition to the above, there are a great number of minor educational journals chiefly of local circulation. Practically every state has such a local journal. In some states two or more compete for patronage. In the same way some of the larger cities possess such local organs. The Bureau of Education at Washington published in 1910 a list of more than 100 educational publications issued in the United States.

**JOURNEYS, SCHOOL** — See EXCURSIONS,  
SCHOOL.

**JOWETT, BENJAMIN** (1817-1893) —  
Teacher, theologian, and educational reformer.  
He was born in Camberwell, London, of a  
family which sprang from near Bradford,  
Yorkshire, and as a boy was addicted to private  
study showing exceptional mental precocity.  
Jowett attended St Paul's School, London,  
1829-1835, under Dr Sleath, who pronounced  
him the best Latin scholar whom he had ever  
sent to the University. At school Jowett learned  
by heart large quantities of Greek and Latin  
poetry and formed the habit of retranslating  
into the classics passages which he had previously  
translated into English. In 1835 he gained an  
open scholarship at Balliol and came into residence  
at the University, October, 1836. Among his  
contemporaries as scholars of Balliol were Dean  
Stanley, Stafford Northcote (afterwards Lord  
Iddesleigh), and Dean Lake of Durham. Among  
the Fellows of the College at the time were  
Tait (afterwards Archbishop) and W G Ward.  
Jowett won the Hertford (University) scholarship  
in 1837, and in 1838 was elected Fellow of  
Balliol while still an undergraduate. He took  
a First Class in Literæ Humaniores in 1839.  
He graduated B.A. in 1839, M.A. in 1842, and  
in the latter year was appointed to a tutorship  
in Balliol College, a post which he held for the  
following twenty-eight years. He took deacon's  
orders in the Church of England in 1842, and  
priest's in 1845. Brought up in evangelical  
opinions, Jowett was plunged at Oxford into the  
midst of the Tractarian Movement and was  
greatly attracted by W G Ward (see Oxford  
Movement). In 1844 he took a leading part on  
the side of toleration of religious opinion in the  
University. He now became acquainted with G  
Hermann

Becker and Ewald, and other famous German  
scholars. Hegel's writings fascinated him. He  
gradually turned to the study of Plato, to which  
he devoted a large part of his life.

For many years theology was his chief occupation.  
An intimate friend of A. P. Stanley, he undertook  
an edition of St Paul's *Epistles* and threw himself  
with vigor into the agitation for university reform.  
He wished to retain the college system, but favored  
an increase in the number of professors. The  
claims of the poor student found in him a  
strenuous advocate. With what he called the  
"gentleman heresy" of university life he had  
no sympathy. He gradually became recognized  
as an authority on questions of public education.  
In 1855 he was appointed to the Regius  
Professorship of Greek in the University. His  
supposed heterodoxy roused against him much  
theological opposition, which for a time deprived  
his chair of a greatly needed addition to its  
trifling endowment. As Professor of Greek,  
Jowett lectured on the *Republic* of Plato and  
the early Greek philosophers, and by his devoted  
attention to his pupils, not only those of his  
own college, won for himself an abiding place  
in the affection of the rising generation. In  
1860 his article on the interpretation of  
Scripture, when published in *Essays and Reviews*,  
excited once again the anger of his theological  
opponents. The controversy deepened his  
spiritual insight and caused him for a time to  
"hold his tongue about theology."

His tutorial labors in college were immense.  
At one time he saw every undergraduate in  
Balliol once a week. His remarkable influence  
is attested by the long list of distinguished  
and devoted pupils who received their  
inspiration from him, and by the stamp which  
he set on Balliol. From 1865 onwards he  
devoted much time to the organization of  
education both in college and in the university.  
Inter-collegiate lectures were arranged. He  
urged the necessity of lessening the expense  
of an Oxford career. He established a hall  
for poor students. He took an active part  
in the rebuilding of the college. He tried to  
enlarge the area from which the University  
drew its students. Elected to the  
Mastership of Balliol in 1870, Jowett  
redoubled his energies both for the  
enlargement of the college and for the  
extension of its usefulness, devoting to this  
work a large part of his private means.  
He interested himself in the development  
of university and secondary education in  
other parts of England. The University  
College at Bristol (now the University of  
Bristol) owed its foundation in large  
measure to him. He encouraged the study  
of Oriental languages in Oxford by  
candidates elected to the Indian Civil  
Service. He greatly improved the health  
of Oxford by taking an active part in the  
better drainage of the Thames valley. He  
encouraged the drama and music in Oxford.  
During a

brilliant Vice-Chancellorship he helped in developing the system of university extension and was chiefly responsible for the erection of the examination schools in the High Street, an important addition to the mechanism of university life.

In 1871 his translation of Plato was published, and later years were largely given to its revision for a second edition. No ordinary translation, this book contained a series of essays and commentaries which comprised the wisdom of a studious and active life. He also completed translations of Thucydides and of Aristotle's *Politics*. No Oxford teacher had a more brilliant circle of pupils or greater influence upon public affairs. He died in October, 1893, and was buried in Oxford.

Jowett's study of Plato had a profound influence upon his educational ideas. It was Plato who confirmed him in the belief that "education comprehends the whole of life and is a preparation for another life in which education begins again." It was Plato who encouraged him to press on men and women the duty of self-education in later life. In Bacon's words, Jowett asked counsel of both times—of the ancient time what is best, and of the later time what is fittest. Those whose privilege it was to work with him in public affairs can never forget the quickness of his insight, his grasp of detail, his courage in action, his indifference to academic hesitations, his severe self-command. With him mere information had been distilled into wisdom. His speech had always the "salt of circumstance," though his plans were touched with a secret idealism. He wrote no systematic treatise on pedagogy, but he was a master of the science and art of education. A hard worker himself, he hated loafing. But he knew that most men can only profitably give a few hours of intense application to their daily studies. Therefore he encouraged moderate athletics. He was a loyal friend of physical science and urged its study in the university. But he was no partisan of scientific as against literary, or of literary as against scientific, studies. He had reached the synthesis where the two are joined in one discipline. He was, perhaps, a little blind to some of the subtler evils of the system of competitive examination, which he did so much to generalize. He knew that examinations are necessary. He had seen the mischief caused by their absence, the danger of dilettante studies, the necessity for most men of a punctually recurring intellectual audit. But perhaps he did not foresee the danger of a too great development of the examination system. As a tutor, his way of teaching was to compel self-knowledge and to excite interest rather than to satisfy it. He disliked sentimentalism. He had Dr Johnson's hatred of exaggeration and conceit. He had a great idea that the welfare and prosperity of the nation depended on the upbringing and education of

the young men of station and ability who would be called upon to bear part in public life. To poor scholars he was a sincere and munificent friend. He was proud of the fact that the success of Balliol had been due to the Fellows having always preferred public interests to private ones. He was a sincere believer in the virtues of college life. But there was nothing monastic in his view of college training. He did not aim at making specialists, but men of affairs, men who would serve God in Church and State. It may be said of Jowett what he said of Plato, that "he had many sides of wisdom, and he was not always consistent with himself, because he was always moving onward and knew that there are many more things in philosophy than can be expressed in words, and that truth is greater than consistency." He would have said of himself, as he said of his master, Plato, that his teaching was "half playful, yet having a certain measure of seriousness."

**JUDGMENT** — This term is employed in a larger and more vital sense and in a narrower and more formal one. In its pregnant sense it means the act (or the power) of weighing facts or evidence, in order to reach a conclusion or decision, or (as is usual with words denoting acts) the result, the outcome of the process, the decision reached by the process of reflective inquiry and deliberation. In this sense judgment expresses the very heart of thinking. All thinking is, directly or indirectly, a part of the act of judging, of forming an estimate or valuation after investigation and testing. The difference in the adequacy of different cases of thinking is due to the care and thoroughness with which the operations of critical summoning and weighing of evidence are performed. The evaluating nature of judgment and its relation to a reasonably reached, intellectually valid conclusion, are suggested by the judicial procedure from which the word "judgment" is derived. There is primarily something at issue, at stake, something which is as yet undetermined, uncertain, but which needs to

be decided. Without a crisis of uncertainty of this sort, without a questionable or problematic situation, there would be no judging. Then there follows the calling and hearing of witnesses, presenting all the facts relevant to settling the matter — that is to say, there are the processes of observation, recollection, etc., which bring in the data or evidence upon which a correct decision depends. Then there is the sifting, comparing, classifying, and relating operation by which is determined the respective force, the authority, to be assigned to this fact or that. This weighing or evaluating process involves the use of the general rules or principles bearing upon cases of this sort that have been established in prior experience. Finally the judgment issues in a decision, or declaration that the case is thus and so, within certain limits of probable error. From this sketch it is evident that judging involves in individualized concrete form all the operations of thinking or reflective inquiry, both material and formal: that is, the material operation by which facts are gathered and the formal one by which the facts are weighed and their meaning determined. From the standpoint of logical analysis, existence and meaning are thus the defining traits of every judgment.

The central position occupied by the training of judgment in the scheme of education is obvious. It may be explicitly stated by calling up to view the errors involved in failing to give it a central position. In brief, these consist, on one side, in the amassing of mere information, through observing and memorizing material which is put to no intellectual use, and, on the other, in merely formal exercises in reasoning apart from consideration of subject matter. In contrast with these counterpart errors, judgments involve the gathering of facts, but also the use of reasoning to compare, contrast, place, and interpret the subject-matter. Only where these two processes are combined (corresponding to the interrelation of existence and meaning) is there any training which is of value either for the practical deliberations of life or for the theoretical pursuit of science. Conditions that work against in the training of judgment are, accordingly, such procedures as the following: The multiplication of isolated sense observations, as in some schemes of object lessons and sense training; the multiplication of logical analyses apart from their bearing on reaching a conclusion; attaching great importance to correct reproduction of things previously learned without employing that material in pursuing some further inquiry; attaching importance to correct results or "answers," quite apart from the mental operations by which the results were reached; exercises where the material and methods are externally dictated, with no opportunity for the employment of judgment in selecting, arranging, and testing, methods in which mechanical skill, automatic rapidity,

and accuracy are set above reflective inquiry — as in many so-called "drill" exercises, methods in which opportunity to commit errors is mechanically excluded, or in which, when committed, they are externally corrected without throwing upon the pupil any intellectual responsibility.

In its narrower and more technical sense a judgment is a statement of a relation between two objects, or between two contents of thought, two meanings. This is the meaning which the term "judgment" has gradually assumed in formal logic, from its standpoint the vitally practical meaning of judgment just expounded is sometimes contemptuously looked down upon as merely psychological in character. From the standpoint of judgment proper the actual operation of thinking as performed in life, the formal statement of a relationship *in abstracto*, is one important stage in the development of a controlled judgment. It marks a summing up, a gathering together of the net outcome of prior reflections. Such formulations are indispensable factors in the adequately performed vital judgment. Because the function of formulation is so important, judgment is not unfrequently identified with the statement of relations, or with the *proposition* (*q v*) J. D.

**JUNGE, FRIEDRICH** (1832–1905) — A German teacher, became prominent through his reform of the methods of nature study in the German schools. Born of an extremely poor family in a small village in Holstein, he prepared for the teaching profession at Segeberg, a seminary of his native province. From his earliest youth he was greatly interested in the study of nature, and when, as a man of forty, he received a position as a teacher in Kiel, he improved his opportunities by attending lectures in zoology and botany at the university, and by working in the laboratories and museums. As the fruit of these studies and of his long experience in the schoolroom he published, in 1885, his *Dorfteich als Lebensgemeinschaft* (*The Village Pond, a Biological Community*), which was read with great interest by teachers all over Germany. In this work he condemned the current methods of nature study, which aimed at mere systematization, and introduced the observation of communities of organic beings, both plants and animals, living under the same conditions and dependent on each other and on their environment. The child's interest was to be aroused by studying the life of an organic community which was near to him, such as the village pond, the meadow, the forest, the swamp, etc., proceeding thence to more remote organic communities, and finally to the aim of all nature study, a clear and sympathetic insight into the unity of all life in nature F. M.

**JUNGIUS, JOACHIM** (1587-1657) — German scientist and schoolman, was born in Lubeck, and studied at the universities of Rostock and Giessen. In 1609 he was appointed as professor of mathematics in Giessen. Three years later he was ordered by his sovereign, the Landgrave Ludwig V of Hesse-Darmstadt, to investigate the new method of teaching promulgated by Ratke (*qv*). He published a very favorable report about the work, in which, among other things, he advocated instruction in the mother tongue. When Ratke was called to Augsburg in 1614, to put his method into practical operation, Jungius followed him there. The result of the experiment, however, proved disappointing, and Jungius returned to his native city of Lubeck in 1615. The following year he again entered the University of Rostock, this time as a student of medicine. He remained for three years, and then went to Padua, where he obtained the degree of Doctor of Medicine. Returning to Rostock, he founded there, in 1622, a scientific society (*naturforschende Gesellschaft*), the first in Germany and in the whole north of Europe, "for the purpose of investigating truth through reason and experience, of freeing from sophistry all arts and sciences which are based on reason and experience, and of promoting them by happy inventions." He thus became one of the first representatives of Baconian ideas in Germany. In 1628 he was called to Hamburg as director of the Johanneum, there he remained until his death. Among his friends were Comenius and Harthib (*qv*). Jungius was a pioneer in Germany in insisting on a truly scientific method of studying nature by means of experiments and induction. He applied his principles chiefly to physics and to botany. In botany he anticipated some of the ideas of Linnæus on the classification of plants. F. M.

**JUNIATA COLLEGE, HUNTINGDON, PA** — An institution founded in 1876 as the Brethren's Normal School and Collegiate Institute, the present name being adopted in 1896. An academy, college, school of education, Bible and music schools, are maintained. The entrance requirements to the college are equivalent to fourteen points of high school work. The college course of four years leads to the degree of A. B. The faculty consists of twenty-three members.

**JUNIOR COLLEGE.** — A term used by the University of Chicago, the University of California, and a few other institutions of higher learning to designate that part of the four-years' college course embraced in the

freshman and sophomore years, the college course being thus divided into a junior college of two years, and a senior college of two years. The outline of instruction, or the requirements as to work and electives, vary in the two divisions, being more largely prescribed in the lower division than in the higher. One object of the division is to make a separation between what is pure college work and what is the beginning of university work, another is to form a basis for the radiation of professional instruction, beginning with the junior year, another is to encourage small colleges of limited endowment to limit their work to that of the junior college, and then make the transfer of their students easily by admitting them to the senior college, and another is to encourage the larger and better equipped high schools to gradually add a thirteenth and a fourteenth year to the high school course of instruction, and thus stimulate the building up of junior colleges in the larger cities. The term has thus, by transfer, also come to mean a two years' course of instruction beyond the four-year high school, and a number of city school systems to-day speak of having the first year, or both years, of a junior college. The legislature of California in 1906 authorized cities to establish such course of instruction, covering two years beyond the ordinary high school course, and a number of city high schools have now added one year, and a few are planning to add two years. A number of colleges in the Mississippi valley have entered into junior college relations with the University of Chicago. With the rapid increase in students in the larger colleges and universities, with the rapid growth of city school systems in equipment and in the ability to provide advanced instruction, and with the shrinking of the endowments and income of the smaller colleges, relatively if not actually, the junior college idea is likely to make much more rapid progress in the next decade than it has in the past. E. P. C.

**JUNIOR NORMAL SCHOOLS** — These are in a sense a revival in a new form of the old six-weeks summer normal institute, common thirty to forty years ago. These new schools are conducted under better auspices and embrace a more definite outline of instruction. Nebraska offers a good illustration of the new movement. This state first founded such schools nearly ten years ago and has so far provided for the establishment of eight such schools. The term of instruction is six weeks in length, and the session is held at some time during the three summer months. The instructors for each such school are selected and the course of instruction is outlined by the Board of Education for the normal schools of the state. County superintendents of schools in adjacent counties may declare any week of the term of the junior normal to be the institute week for their county, and appropriate

their institute fund to assist in its maintenance. The different schools are supported from state and county institute funds. A few other states, such as Idaho and Louisiana, have analogous summer institutes. The six-weeks summer sessions of the regular state normal schools is a step farther in advance, as in such cases the normal schools have the buildings, equipment and teachers of the regular school for the work of instruction. E. P. C.

**JUNIOR REPUBLIC** — See **GEORGE JUNIOR REPUBLIC**

**JUNIUS, ADRIAN** (c. 1512-1575) — A learned Dutch scholar, of great repute for his knowledge in physic, classical writers, history, philosophy, and in modern languages. Had he lived, it was proposed to give him a professorship in the new university at Leyden. He was born at Hoorn in Holland. He pursued his studies at Haarlem, Louvain, Paris, and Bologna, and in the last-named university took the degree of M.D. He traveled in Germany, and lived in England 1543-1548.

He settled finally as a physician at Haarlem, where he was head of the College. He was a man of great erudition, and had a prodigious memory. The following are his chief educational works —

(1) Edited books of Ausonius, Cassius (animal medicine), Eupapius, Hesychius (*Lexicon*), Juvenal, Lucan, Martial, Nonius, Marcellus, Plautus, Plutarch, Seneca, Virgil. (2) Edited an *Epithetorum*. *Epitome* of J. Ravisius, usually called Textor. (3) *Adagiorum Centuriæ VIII cum dimidia Basilæ, Froben*, 1558 [an addition to Erasmus' Collections of *Adagia*]. (4) *Emblemata*, 1565. (See **EMBLEMS**, and Mr. Henry Green in his reprint of Whitney's *Choice of Emblems*, p. 250). (5) A *Greek-Latin Lexicon*, with dedication to Edward VI., 1548. (6) *Nomenclator*, 1557, in Latin, Greek, German, Dutch, French, Italian, Spanish. This work was translated into English by J. Higgins, London, 1585. The *Nomenclator* is a dictionary of all necessary words arranged not alphabetically, but grouped under subjects. Adrian's *Nomenclator* is, therefore, a forerunner of J. A. Comenius' *Janua Linguarum*, but without the descriptive sentences. There are many in common, *eg* living creatures, animals, fishes, all kinds of food, trees, vegetables, apparel, buildings, parts of ships, tools, terms in war, games, money, the elements, God and spirits, handicrafts, trades, affinities, etc. The *Nomenclator* is thus clearly a source of the *Janua Linguarum* of Comenius, though the form was suggested by the Jesuits' (Salamanka) *Janua Linguarum*. It may also be mentioned that Eilhardus Lubinus (*q.v.*)

in his *Epistolary Discourse* before his edition of the New Testament refers to this work of Junius, and Brinsley (*q.v.*) in 1612 recommends the repetition of a few words daily out of the *Nomenclator*. F. W.

**JUNKIN, GEORGE** (1790-1868). — First president of Lafayette College, graduated at Jefferson College in 1813. He engaged in the ministry, became interested in agricultural education, conducted the Manual Labor Academy at Germantown (1830-1832), was president of Lafayette College (1832-1841 and 1844-1848), president of Miami College (1841-1844), professor in Washington College (1848-1860) and Lafayette College (1865-1868). Author of several works on religious education.

W. S. M.

**JUSTIN MARTYR** (110-165 A.D.) — The earliest Christian apologist and the first Christian after the original Apostles whose writings are known with sufficient fullness to enable us to form a clear picture of him and his system. He was born in Shechem of heathen parentage and received a thoroughly Greek education with added advantages of foreign travel. He became familiar with a wide range of Hellenic culture and has left, in the opening pages of his *Dialogue with Trypho*, an interesting description of his studies and philosophical experiences. He was successively a Stoic, a Peripatetic, a Pythagorean, and a Platonist. After his conversion to Christianity, he saw no reason to forego the pursuit of philosophy nor abandon the distinctive dress of a philosopher. He simply embraced the Christian religion as the true philosophy. He did not break with philosophy, nor regard it as the enemy of Christianity, but rather as the handmaid of the truth. At Ephesus and at Rome, where he resided for some years, he held himself ready for discussion with every comer and devoted himself to the defense and dissemination of the Christian faith, drawing to himself many pupils and disciples who afterwards became famous champions of the cross. He was at once a philosopher and a saint. He used the dialectic method in the spirit of Socrates, but his mental attitude was distinctly Platonic. His apologetic method appeals strongly to men of the present day. While the Antonines were reigning as "philosophers," he was building up a great new system of Christian philosophy which could fearlessly appropriate everything that had ever been rightly said and done as its own and throw the light of revelation over the doubts and contradictions of the past. His writings are of the utmost value, not only as apologetical and theological treatises, but also as pictures of Christian life and thought before the Canon of the New Testament was completed, the main outlines of which are luminously drawn by him. His *Dialogue with Trypho, the Jew*,

modeled after the dialogues of Plato, contains all the vital points of Christian theology, and is a defense of Christianity as the successor of Judaism and of the Christian interpretation of the Old Testament. His *Apology*, addressed to the Emperor in defense of his fellow-Christians, is the noblest representative of early Christian literature. He wrote an essay on psychology in which he differed radically from Plato and the Greek philosophers on the nature of the soul. W. R.

## JUVENCUS, CAIUS VELTIUS AQUILINUS

— A Spanish priest of noble family, who composed a poem in four books consisting of about 800 hexameters in each book. The name of this Latin poem was *Historia Evangelica*, written about the year 330 A. D. Juvencus is the first of the conspicuous Christian Latin poets. "The [classical] lyric no longer existed, the mythological epic had been sung out, and an epic treatment of the New Testament was a new and daring undertaking to be approached only in a spirit of reverence especially as regards the subject matter" (J. T. Hatfield's *Study of Juvencus*). The story of the gospels is given in hexameters, closely following the old Latin version of the Bible, though at points in the New Testament Juvencus evidently has consulted the original Greek. The closeness of his following of the Scripture text has taken away from any possibility of originality of treatment of the subject matter. He especially follows St. Matthew, and ends his story where St. Matthew ends his. Juvencus is of importance as an early experiment in imitation of a classical model. He takes Vergil as a model, and as Dr. Hatfield's minute study of Juvencus shows, "the direct citations include every book of the *Georgics* and *Aeneid*, and not a few passages in the *Ecllogues*. He never quotes entire more than half a verse and thus but rarely." The combination of Christian subject matter directly from the gospels and the close imitation of Vergilian style made Juvencus a popular educational work in the Middle Ages, a popularity which continued into the sixteenth century. Colet in drawing up the Statutes for St. Paul's School, 1518, requires that the boys be taught specially in "*Christyn authors* that wrote theyre wysdome with clene and chaste laten other in verse or in prose," and specifically names Juvencus (with other authors) to serve as school authors to be read.

The preface or prologue to the *Historia*

*Evangelica* should be mentioned as rising to a higher level of poetic inspiration. In it Juvencus speaks of the transitoriness of all earthly material things. Nevertheless, men are celebrated through long ages for their deeds and lives, and poets who celebrate these deeds themselves reap fame. The glory of Homer and of Vergil is eternal. Juvencus' song is the life and work of Christ. Even the fires which will destroy this world will not touch that, and perchance, even Juvencus' book with such a subject will save him from the fire, and he ends with a prayer for divine assistance to speak worthily on his great theme. This desire of fame is a forecast of the early Renaissance spirit. F. W.

## JUVENILE DELINQUENCY, JUVENILE COURTS, AND JUVENILE PROBATION —

"Juvenile Delinquency" is a term generally used to refer to the conduct of children of all ages when it runs counter to the public standards of propriety. The term has also a legal and technical meaning, as defined in the penal law of New York State since Sept. 1, 1909, which says that a child between the ages of seven and sixteen who commits any act or omission which in the case of an adult would be a crime not punishable by death or life imprisonment shall be deemed guilty of juvenile delinquency and punished in the same manner as an adult would be for the same offense except when the law provides specifically other punishment for children under sixteen (L. 1909, ch. 478, New York). The object sought by the New York law, which is similar to that in other states, is to relieve children who commit minor offenses from the stigma and disabilities of a public record of crime so as to give them the maximum chance and encouragement to make their future conduct normal. The criminal law now very generally holds children under seven incapable of committing crime in the legal sense, and a child between seven and fourteen years of age is entitled to the presumption of innocence of a guilty knowledge that he was doing wrong, though at this age *mens rea*, or intent to do a criminal act, may be shown by evidence and the child held to full responsibility.

It is less than a century since the attitude of the laws of England and the United States, and the practice of the courts in condemning and sentencing very young children to barbarous penalties for trivial offenses revealed little knowledge of the mental life of children and less regard for their possible reformation.

## JUVENILE DELINQUENCY

Through association with hardened criminals and every form of vice during the period of police custody, court proceedings, and subsequently in jails and prisons when under sentence, the record reads like a deliberate attempt on the part of the State to manufacture criminals. Happily a very different effort is now made in all civilized countries, based on a better understanding of the psychology of child life and a better appreciation of the environmental factors in fixing responsibility for crime, which has for its aim reformation and prevention rather than punishment. Now every possible device is sought to keep the child away from the contaminating influences of police methods, criminal court procedure, jails, and prisons, and to deal with juvenile delinquency through the educational machinery of a children's court, with its special juvenile probation officers, and with the cooperation of parents, school authorities, and all public and private agencies dealing with children. Only a beginning has been made and the change in purpose necessitates so many new adjustments which only time can bring about that doubtless much of our present achievement in dealing with juvenile delinquents will seem to future generations to fall as far short of justice to the child as the record of the past looks dark and dreary to us.

**Character and Extent of Juvenile Delinquency** — Very trivial offenses may constitute delinquency, and the present tendency in juvenile legislation is to enlarge the scope of the law in order to bring conduct that may easily lead to more serious crime under preventive and probational control. Thus the Colorado law includes under delinquents persons under sixteen years of age charged with visiting saloons, jumping on moving trains, wandering aimlessly about the streets at night or about railroad yards, using vile or obscene language, associating with immoral persons, as well as those who violate state laws and city or village ordinances. Truancy is usually dealt with in the first instance by the truant officer or by the school authorities, and therefore does not appear often in court cases. For the entire country it would doubtless appear numerically near the top of the list of offenses charged against juvenile delinquents.

Owing to the varied and changing definitions of the law, no general or comparative statistics of juvenile crime throw any satisfactory light on the most frequent forms of juvenile delinquency.

The following table gives a summary of the business of several of the more important and best organized juvenile courts, covering the year 1908, as taken from a report of Miss M. Z. Doty to a subcommittee of the New York Child Welfare Exhibit. The figures are approximate and not comparable because of the different bases of organization and procedure in the different courts, but they serve to show the aggregate number of children coming before these courts,

## JUVENILE DELINQUENCY

and something as to the probable serious or trivial character of the conduct that brought them into court.

JUVENILE COURTS	TOTAL	SENT TO REFORMATORY	PUT ON PROBATION	SENT TO HOMES FOR NEGLECTED CHILDREN	RELEASED <sup>1</sup>

Dr G. Stanley Hall gives a remarkable summary of the record evidences of juvenile faults, immoralities, and crimes in *Adolescence* (Vol. 1, ch. 5, pp. 325-410), which gives data for many countries and presents many considerations of value concerning the nature and character of juvenile delinquency. In New York City two thirds of the cases brought into the Children's Court were technically charged with violation of section 720 of the penal law, which in effect makes playing baseball in the city streets or any form of annoyance in public places and on public conveyances a misdemeanor. The majority of cases in the children's courts of other cities which children are summoned for, or charged with, like minor offenses, more often reveal changes in the natural environment of the child and the absence of proper provision for the natural, and, under slightly changed conditions, harmless acts of normal child life rather than a depraved or inherently criminal disposition.

A recent study of delinquent children brought to court in Chicago during the first ten years from June 1, 1899, when the first juvenile court in the United States was established in Chicago, to June 30, 1909, covered a total of 14,183 children, about equally distributed over the ten years. Of these, 11,413 were boys and 2770 were girls. Up to 1905 the

## JUVENILE DELINQUENCY

court had jurisdiction only of children under sixteen years of age, but a change in the law that year gave the court jurisdiction up to seventeen for boys and eighteen for girls. Among the boys 22 per cent were fifteen years of age, 18.6 per cent were fourteen years, 14.6 per cent thirteen years, and 13 per cent twelve years of age. The largest number of girls range from fourteen to seventeen inclusive, with the maximum per cent 26.3 at fifteen years.

An analysis of the offenses which were the cause of these children being brought to court is interesting, and shows that more than half of the delinquent boys were charged with violation of rights of property ("stealing from the railroad" heads the list; stealing money comes second, junk, third, shop-lifting, fourth, breaking into empty buildings, fifth, stealing from parents, stealing and driving away with horse, motor, or bicycle, stealing gum, fruit, candy, or tobacco, stealing pigeons, ducks, stealing newspapers and miscellaneous thefts follow in due order). A careful study of these cases led the investigator, Dr. Breckinridge, to comment: "Without minimizing the dangers into which a boy may be led, it seems clear that a considerable number of these acts are not vicious, but are performed in a spirit of harmless adventure and without realization of their possibly serious consequences."

Next after stealing, to which is credited 50.8 per cent of the offenses, comes incorrigibility (21.7 per cent), disorderly conduct (16.2 per cent), malicious mischief (6.5 per cent), vagrancy (2.3 per cent), immorality (1.6 per cent), dependent charges, — drunkenness of parents, lack of care, etc. (8 per cent), truancy (7 per cent), miscellaneous offenses (1.4 per cent). This makes the total 102 per cent. Two per cent represents cases counted twice, that is, brought into court under two different charges. The total number of cases brought into court was 11,641.

Of the girls (2,770) the offenses are classified as follows: stealing (15 per cent), incorrigibility (42.8 per cent), immorality (31.4 per cent), disorderly conduct (6.7 per cent), malicious mischief (2 per cent), vagrancy (1 per cent), dependent charges (3.3 per cent), miscellaneous (1 per cent), not reported (4 per cent). The charge of immorality is somewhat different from that in the case of boys, and usually signifies that the girl has been going in bad company, or in the street day and night, or has a bad reputation, or is staying away from home in company with vicious people, is strongly suspected of being immoral, or is charged with using vulgar and obscene language. Every effort is made to protect girls from the charge of immorality, and where the evidence is not clear the offense charged is usually incorrigibility.

In the treatment of the cases just cited 59.3 per cent of the boys and 37.5 per cent

## JUVENILE DELINQUENCY

of the girls were put on probation. Twenty-one and three tenths per cent of the boys and 51.5 per cent of the girls were committed to institutions, and 16.9 per cent of the boys and 10 per cent of the girls were cases continued indefinitely or dismissed, while the remaining cases (2.5 per cent boys and 1.4 per cent girls) were disposed of otherwise.

Another interesting fact in connection with the analysis of these Chicago cases shows that 67.9 per cent of the boys and 79.7 per cent of the girls appeared in court only once in this ten-year period, while 86.2 per cent of the boys and 96.7 per cent of the girls were in court twice or less.

**Causes of Juvenile Delinquency** — Much may be inferred as to causes of juvenile delinquency from what has been said as to its character and extent. Specific and convincing statistical evidence is not available, but recent studies of cases that come before juvenile courts in the large cities indicate that environmental conditions play the largest rôle. Congestion in living quarters, the absence of playgrounds or any outlet for normal physical activities of youth, inadequate or ill-adapted schools, and commercialized amusements which exploit the normal desire for recreation, taken collectively constitute a group of environmental conditions which in the large city play havoc with the growth and development of childhood.

Parental neglect and irresponsibility plays, perhaps, the second most important rôle. This in turn is attributed in part to the long working day of the father, to widowhood, and to conditions of poverty that require the mother to be away from home at work either for long hours or at hours when the children are free from the control or supervision of the school. The juvenile court as a public agency to deal with delinquent and neglected children has been extended to cover neglect, and in many states, as originally in Colorado, the parent or parents or legal guardian who is responsible for, or by any act encourages, causes, or contributes to the delinquency of the child is guilty of a misdemeanor. This enables the court to bring the parent into court on a charge directly connected with the delinquency of the child, and by suspending sentence the parent can practically be made the agent of the court to carry out the sentence of the court under the superintendence and direction of the court.

Poverty and dependence would seem to be responsible for a great deal of delinquency if we regard the records of the court as its sole measure. Many persons believe that children ought not to be brought into court at all on a charge of destitution or poverty, and it is certain that the courts are always embarrassed to know how to deal with such cases, which would seem more properly to belong either to private charities or to officials of the poor law than to juvenile courts. Definite commitments to institutions in the case of orphan children or of

children who must be taken from their parents because of improper guardianship would still have to be settled in a court of justice and should of course be put within the jurisdiction of a juvenile court

**Treatment of Juvenile Delinquency — The Juvenile Court.** — The movement for separate courts for children began in Massachusetts in 1869, and although measures were taken to secure them, no progress was made. The idea was, however, adopted in Adelaide, South Australia, in 1898, and soon after this example was copied in Toronto. As now known, the first juvenile court in the United States was organized in Chicago in 1899, and is now an institution very generally found in the larger cities of the country, as an adjunct of their judicial system. It has spread as an institution very rapidly even beyond the borders of the United States, and is now recognized in England and throughout Europe as a distinctive American contribution to social administrative progress. In many places, as in New York City, it is grafted upon the regular judicial system. In Manhattan, the New York Children's Court, as it is called, is known as the children's part of the second division of the Court of Special Sessions. Two of the judges of the Court of Special Sessions sit in turn, three months at a time, in the Children's Court, and it has its regular quota of court officials and police officers. Until recently it had no probation officers, but agents of the Society for the Prevention of Cruelty to Children acted as official investigators and parole officers of the court, now there are eighteen probation officers. The procedure of the court is that of the criminal court, with slight modification depending upon the attitude and personality of the judge on the bench. This is not a good sample of what the Children's Court ought to be, as conceived by those who regard it as a new device for handling children in a new way without necessarily implying any new legal principles or any radical changes in our jurisprudence.

The model juvenile court seeks to express a new attitude of society toward juvenile delinquency which will make the welfare of the child and the good of the State sufficient grounds on which to base the right of the court to control the custody of the child and to permit the court, if necessary, to take the child from its natural parents or guardians, provided its welfare is the determining factor. The juvenile court thus becomes, not an instrument for prosecuting a criminal, for the juvenile delinquent henceforth is not to be regarded as a criminal, but the agent of the State for the purpose of protecting and conserving a great and fundamental interest of the State, which is the well-being of each individual child whose well-being for any cause is not properly safeguarded by its natural protectors or guardians.

The juvenile court, organized as part of the

administrative machinery of the government, can also serve to bring into effective cooperation for the better protection of the child and the improvement of its surroundings through probation and other proper methods and court procedure every child-helping resource of the community, — parents, teachers, social workers, playgrounds, neighborhood centers, settlements, churches, and institutions of all kinds. It can secure for the child a physical examination and proper treatment for physical defects. It can do all of these things under the continuous and wise supervision of the court authorized at any time to intervene on behalf of the welfare of the child and exercise the full compelling authority of the State. The courts of last resort have construed the laws creating juvenile courts so as to uphold this broad exercise of power on the ground that this is a power which has been used from earliest times by the English chancellors, who in some of the oldest cases held that the right to take a child from the custody of its parents existed where the father ill-treated or was cruel to infant children, was drunken or debauched, or whose domestic relations tended to corrupt and contaminate his children.

To separate the child offender from the adult criminal, to make the court an agency for rescue as well as punishment, and to bring home to the parent a realizing sense of the great responsibility for the wrong-doing of his child, and to avoid the necessity for commitment of children to jail, — are among the prime objects of the juvenile court.

England through the Children's Act of 1909 (see CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF) has made provision for juvenile courts by authorizing the appointment of special children's magistrates, and while, as yet, little progress has been made in providing different rooms or buildings from those in which other sittings of the court are held and thus giving to the juvenile court a distinctive character of its own, the legal machinery exists, and only a more liberal construction of the act by the home office is necessary to accomplish this result.

A great deal depends on the physical machinery of the juvenile court for its best success. A separate building constructed on different architectural lines from the traditional courthouse and separated from the machinery associated with police arrests and prosecuting methods is desired. Even in densely populated areas the impossibility of providing separate courts in sufficient numbers to be readily accessible for all the children suggests the further necessity of creating some local agencies other than police courts for hearing and sifting minor complaints, sending only the more serious ones to the children's courts.

The existing practice in many communities of assigning the regular judges and using the regular courthouse for part time in the work

of the children's court may be an intermediate step to an improvement on existing methods where there is no children's court, but it is not to be commended as a solution of the difficulties or as a way of achieving the aims of a proper juvenile court. The detention house, or a place where children may be kept in custody pending trial or investigation of their cases, or for brief periods of necessary confinement, is an important adjunct of the children's court, and should differ as much from the ordinary jail as the children's court is different from the regular court. The essence of juvenile court procedure, however, consists in a proper system of probation.

*Juvenile Probation* — The New York Probation Association defines probation as a means of disciplining and seeking to improve offenders without committing them to correctional institutions. This is applied both to children and adults in New York State, and now in many jurisdictions. The "fine" system is rapidly losing favor, especially in dealing with children, where the parent invariably paid the fine and was the one punished, or the child went to jail in default of payment and was put under influences likely to instil or develop criminal tendencies. Some method of treatment that will restrain children from continuing in evil ways and at the same time help them to overcome bad influences and encourage them to attend school regularly, keep away from harmful places and unfit companions, and conduct themselves with some regard for the rights of others is so universally needed, and probation, properly safeguarded in a way to secure appointment of efficient probation officers, so admirably meets this need, that its adoption is spreading rapidly. Massachusetts enacted the first probation law in 1878, which for two years applied only to Boston, then to the entire state, and both to juvenile and adult offenders. Illinois, Minnesota, and Rhode Island were the next states to adopt probation laws in 1899, more than twenty years after Massachusetts had pointed the way. New Jersey and Vermont followed in 1900, which brought the list up to six states, but by the end of another decade (1910) thirty-eight states and the District of Columbia applied probation to children, and twenty of these states to adult offenders.

The principles of probation are simple, but their application difficult. So much depends on the personality of the probation officer. In many places such officers are appointed as part of the spoils system in politics, and even where, as in very few cases, civil service appointments are made, it is difficult to secure competent persons and to get adequate appropriations for the payment of enough probation officers so that efficient work can be done without overburdening the probation officer with more cases than he can handle with due regard to the delicate nature of the work and thoroughness in its execution. Several states, like Massachusetts

and New York, have provided for state supervision of probation work through a state probation commission, and in this way secure more uniform and better results.

Volunteer and unpaid probation officers are relied upon in some communities to perform such work. They can be used as aids to public salaried officers, devoting their whole time to their professional duties. The paid probation officer serving as a public official under state supervision is essential to secure the best results, and the volunteer can best serve as an aid and supplementary force. The expense of the probation system is not large, and when considered in relation to the saving in the cost of maintenance where persons are put in jails or public institutions, it is a real economy. The "Big Brother" movement was started in 1904 by the Men's Club and Bible Class of the Central Presbyterian Church of New York through the efforts of Mr. Ernest K. Coulter, Clerk of the Children's Court of Manhattan, to secure a Protestant probation officer to look after Protestant children in the court as Jewish and Catholic children were being looked after by representatives of their own religious bodies. The idea of the movement is that a man shall take one boy, make a friend of him, and help him and his family in any way he can, that is, be "a big brother" to him. The proper assignment of boys from the court to the most suitable persons among volunteer big brothers, the securing of records and reports of what is done with the boys and the instruction and guidance of big brothers demands a central organization and supervision which has led to the incorporation of a board of directors. The cooperation of the Y.M.C.A. and the part use of its plant for big brother boys has been secured and plans have been considered to organize the movement on a national scale, but thus far it has been difficult to get sufficient financial support to test fully its possibilities. A woman's auxiliary known as the "Big Sisters" has been started to deal with girls.

**Recent Legislation** — The statutes enacted in 1910 on probation, juvenile courts, adult contributory delinquency and dependency, and juvenile detention homes are cited by chapter and date in the report of the New York Probation Commissioners for 1911, while similar statutes for earlier years are given in previous reports of that commission. In 1910 adult contributory delinquency laws were enacted in Virginia, Rhode Island, New York, and Kentucky, while the probation system was extended or adopted for the first time in the District of Columbia, Kentucky, Louisiana, Massachusetts, New York, Vermont, and Virginia, and statutory provision for detention homes was enacted in Maryland and New Jersey. **KALAMAZOO COLLEGE, KALAMAZOO, MICH** — A coeducational institution, chartered as the Michigan and Huron Institute, in 1833, and later changed to the Kalamazoo Literary Institute. For a few years following 1837 the school was affiliated with the University of Michigan In February, 1855, the institution was chartered as a college. Women were, from the first, admitted on equal terms with men. A theological seminary originally planned was early abandoned The Board of Trustees is a self-perpetuating body of thirty-six, elected in three classes, one class being chosen each year to serve three years There are no fraternities. Presidents of Kalamazoo College have been the Rev J A B Stone, 1855-1863, John M Gregory, 1864-1867, the Rev Kendall Brooks, 1868-1887, the Rev Monson H Wilcox, 1887-1891, Theodore Nelson, 1891-1892, and Arthur Gaylord Slocum, 1892 The institution maintains undergraduate courses leading to the bachelor's degrees in arts, and science, the entrance requirements are fifteen units The degree of A M is given for one year's graduate study in residence. Grounds, buildings, and equipment are valued at \$142,000 The productive endowment is \$460,000, yielding an annual income of \$22,000 There are (1912) thirteen members of the instructing staff The enrollment, in 1911-1912 was 186 C. G.

**KANSAS CITY UNIVERSITY, KANSAS CITY, KAN** — A coeducational institution established in 1896 under the auspices of the Methodist Protestant Church It includes Mather college, college of theology, college of music, Kansas City Normal School, Wilson High School, school of elocution and oratory and Kansas City Hahnemann Medical College Students are admitted on meeting the entrance requirements of fifteen units The degrees of A B, B S, Ph D, and B L are conferred The degree of B D is conferred in the theological department, for which the entrance requirement is the A B degree The faculty consists of fifty-six members, of whom forty have the rank of full professor. In 1910-1911 the enrollment of students was 445, of whom thirty were in the college, sixty-eight in medicine, and thirteen in theology The faculty consists of fifty-six members

**KANSAS STATE AGRICULTURAL COLLEGE, MANHATTAN, KAN** — An institution organized in 1863 as a result of the Morrill Land-Grant Act of Congress of 1862, and by the donation to the state of the grounds, buildings, and equipment of Bluemont Central College, founded in 1858. The college offers facilities for a liberal or a technical education The faculties include 186 professors, instructors, and assistants, organized into four divisions or schools, viz. Division of General Science, Division of Agriculture, Division of Mechanic Arts, and Division of Home Economics Four-

teen four-year courses, each leading to a degree, are offered in the several divisions. Graduate courses lead to the master's degree. Preparatory courses are offered, and also short courses of twelve to four weeks each, in agriculture, dairying, and domestic science. A department of college extension employs a staff of fifteen specialists, who devote their whole time to extension work consisting of lectures, farmers' institutes, social center work, rural education, correspondence courses, and highway, bridge, and drainage engineering. An agricultural experiment station with a central station at the college and four branches had an annual budget for 1911 of \$102,500. An engineering experiment station conducts investigations of engineering problems. The campus consists of 160 acres, and the experimental farms of 5130 acres. The college has twenty buildings devoted to instruction and laboratory purposes. The library contains 60,000 volumes. The total budget for 1911 amounts to \$563,000. The enrollment of resident students for 1910-1911 was 2407.

**KANSAS, STATE OF.**—First organized by Congress as a separate territory in 1854, and admitted to the Union as the thirty-fourth state in 1861. It is located in the north central division, and has a land area of 81,700 square miles. In size it is about the same as that of Minnesota and one third larger than all the New England states. For administrative purposes the state is divided into counties, and these in turn into cities and school districts. In 1910 Kansas had a population of 1,690,949 and a density of population of 20.7 per square mile.

**Educational History.**—The Jesuits were the first teachers in the territory, opening schools at a number of places for the instruction and conversion of the Indians. A white school was opened at what is now Kansas City, in 1844, but the school which is usually regarded as marking the beginning of free schools in Kansas was opened at Lawrence in 1855.

Four constitutions were prepared by different parties and conventions, viz in 1855, 1857, 1858, and 1859. The constitution of 1859 was finally accepted by Congress on the admission of the state. In each of the four constitutions, provision was made for a state system of education, and somewhat similar provisions with reference to education were contained in each of the four. In 1855 school trustees were required to report to the Secretary of State.

In 1857 a territorial superintendent of schools was appointed to look after the school lands, though little was done toward the opening of schools before 1859. In 1858 county superintendents were provided for, but the office was abolished the next year. In 1860 township trustees were directed to divide their townships into districts and the district system was definitely established. For each district

three teachers and an inspector were to be elected for one-year terms. During 1861 reports show that the schools in existence were mostly subscription schools or private enterprises, no state aid was granted that year and only twelve counties made any returns as to schools. A law providing for a state one mill tax was enacted in 1861. In 1862 reports from twenty-eight counties were received. Between 1855 and 1860 as many as eighteen universities and ten colleges were chartered by the legislature, only three of which survived, two of the three becoming state institutions.

In the constitution of 1859 definite provision was made for a State Superintendent of Public Instruction and for county superintendents, for the preservation of the school lands and for a board of school fund commissioners, and for the establishment of a state university and the preservation of its funds. The educational provisions of the 1859 constitution have remained unchanged to the present time. After the settlement of the slavery difficulties, the eastern portion of the state began to fill up, and the increase in population was still more rapid after the close of the Civil War. The number of original school districts in 1865 was 222, in 1866 it was 986, and in 1870 it was 2068. In 1863 the first teachers' institute was held, and the State Teachers' Association was organized. In 1863 Lawrence University, chartered in 1859, became the State University of Kansas (*qr*), Blumont College, chartered in 1858, became the Kansas State Agricultural College (*qr*), and the bill establishing a state normal school was signed. In 1864 the issuance of bonds for school buildings was first authorized, and the State Superintendent was directed to hold a teachers' institute in each senatorial district in the state. In 1868 the holding of teachers' institutes was changed from one in each senatorial to one in each judicial district. In 1869 the examination of teachers was taken from the county superintendents and given to a county board of examiners of three, of which the county superintendent was the chairman. In 1870 a district tax for library purposes was authorized. In 1870 a second normal school was established at Leavenworth, in 1872 one was established for colored students in connection with Quindaro University, and in 1874 a third school was established at Concordia. In 1876 the appropriations for all schools were cut off, and all but the one at Emporia were definitely abandoned. The land endowment saved Emporia, and appropriations for it were resumed a few years later. In 1873 the State Board of Education was created and given power to examine teachers for state certificates. In 1877 a four-weeks teachers' institute was made obligatory in each county, and the control of the institute was transferred, in part, to the county superintendent. About 1870 the

movement for public high schools began, and in 1885 the State University abandoned its preparatory department, after which the development of high schools was rapid. In 1897 a state textbook commission was provided for, in 1899 high school books and school supplies were also to be adopted, and in 1901 it was made unlawful for any one to offer to sell to trustees any book, map, chart, or piece of apparatus not approved by the commission and having a minimum price fixed by them.

In 1903 an efficient compulsory education law was enacted, and an extra tax for industrial training authorized. In 1905 the State Board of Education was given power to prescribe a course of study for the schools of the state, a good child labor law was enacted, and a tax for county high schools was provided. In 1907 educational requirements for the office of county superintendent were added.

In 1909 normal training in high schools and academies was provided for, and \$50,000 state aid voted for this purpose, the school land laws were revised; the Barnes high school law validated, and provision was made to license business colleges to canvass for students in the counties. The legislation of 1911 was the most important enacted by any legislature. The minimum term was raised from five to seven months, and state aid granted to weak districts; the standards for certification were to be increased gradually, and the State Board of Education given power to name and to increase requirements, consolidation of districts, and the provision of transportation were made easier, city boards of education were reduced in number, and made elective at large, township high schools were authorized, the high school normal training law of 1909 was extended and grants for agricultural instruction added; free high school tuition for rural pupils was provided, joint county institutes were permitted; and the salaries of county superintendents were materially increased.

**Present School System** — At the head of the school system of the state is a State Superintendent of Public Instruction, a State Board of Education, a Board of School Fund Commissioners, and a School Textbook Commission. The State Superintendent is elected by the people for two-year terms. He has general supervision and management of the educational interests of the state, gives official opinions to the county superintendents, prepares all blanks and forms, and edits the school laws biennially, visits each county biennially, and makes a biennial report to the Governor, apportions the school fund to the counties, and advises with the county superintendents as to the time and place of holding their normal institutes, and the selection of an institute conductor. The State Board of Education consists of the State Superintendent, the Chancellor of the University of Kansas, the President of the State Agricultural College, the President

of the State Normal School, and three schoolmen, appointed by the Governor with the consent of the Senate and for two-year terms. This Board meets at its own pleasure, and its chief function is to prepare uniform examination questions for use in the county examinations; to examine teachers for state certificates and state diplomas; to approve colleges and normal schools, both within and without the state, and place them on the accredited list for the exemption of their graduates from all or part of the state examinations; and to prescribe standards for the certification of kindergarten and manual training teachers, and to prescribe the course of instruction in manual training schools.

The State Superintendent together with the Secretary of State and the Attorney-General constitute the Board of Commissioners for the management and investment of the state permanent school fund, the normal school fund, and the university fund. The State Superintendent is Secretary of the Board. All school districts issuing bonds must first offer them at par to the Commission, thus insuring that all the school funds may be kept safely invested all the time.

The School Textbook Commission consists of the Superintendent of Public Instruction, *ex officio*, as chairman, and eight persons, appointed by the Governor for four-year terms, the Senate approving, and not more than five from the ranks of any one political party. This Commission adopts a uniform series of textbooks for the elementary and high schools of the state, and fixes the price at which they may be sold. Maps, charts, globes, and apparatus must be similarly adopted and a minimum price fixed. Any city, town, or district may vote to furnish free books to its pupils, but the use of the adopted books is made obligatory upon all.

For each county there is a county superintendent, elected by the people for two-year terms. He is required to visit schools, keep detailed records of many kinds, make quarterly and annual reports to the State Superintendent, apportion the school moneys to the districts, determine and change school district lines, and discontinue depopulated districts, hold an annual normal institute of four weeks in length, divide his county into from one to five truancy districts and nominate a truant officer for each to the county commissioners, to open schools, employ teachers, and levy a school tax sufficient to maintain five months of school in case school directors fail or refuse to do so, and to act as agent and supervisor of the orphan and reform school pupils indentured in his county, visiting each twice a year and reporting as to their condition and progress. For his services he receives a salary of from \$600 to \$1800 a year, varying with the school population of his county. The county superintendent together with two competent persons,

holding high-grade teachers' certificates and appointed by him, constitute the county board of examiners. This board conducts quarterly examinations, using questions prepared by the State Board of Education, and grants four grades of county teachers' certificates. Cities of the first and second class are exempt from the county examinations, and any school district employing ten or more teachers may have its own board of examiners and examine its own teachers. Holders of state certificates and normal school certificates are exempt from such local examinations.

The counties are divided into school districts, each having a district board, consisting of a director, a clerk, and a treasurer, each elected for three-year terms. Cities having a population of 15,000 or over constitute cities of the first class and are governed by boards of education of six members elected at large. Cities of from 2,000 to 15,000 population constitute cities of the second class, and are governed by boards of education of six members also elected at large. Cities of 250 to 2,000 people constitute cities of the third class, but, unless provided for by special law, these are governed as school districts. The treasurer of the board has charge of the money of the district or city, and the clerk keeps all records and makes an annual report to the school meeting and to the county superintendent. An annual school meeting is provided for, and its powers set forth. The annual meeting of the district may by vote, if the county superintendent concurs, discontinue its schools, and pay an adjoining district to teach its pupils for one or more years, and still retain its integrity as a district, or it may vote to annex the district to an adjoining district or city, or to consolidate its schools with those of one or more other districts.

**School Support** — The state originally received the sixteenth and thirty-sixth sections (2,801,306 acres) for common schools, two townships (46,080 acres) for a university, 90,000 acres for an agricultural and mechanical college, and 30,380 acres of salt lands for a normal school. The common school lands have been sold and a permanent common school fund of \$8,500,000 has been built up. So large is the number of school children in Kansas that the income from this fund is worth only about ninety cents per census pupil, five to twenty-one years of age, per year. It is apportioned to the counties and from the counties to the districts semiannually on this basis. The one-mill state tax enacted in 1861 was later repealed. Strong efforts have been made within the last ten years to secure a new state school tax, but so far they have been unsuccessful. The university lands have produced an endowment of \$145,000; the agricultural college lands, \$500,000; and the normal school lands, \$270,000. The chief reliance of the schools is on local taxation, which may go up to 4½

mills. District boards must levy up to that rate if necessary to maintain a seven months' school. Cities may also levy local taxes for schools up to 6 mills if of the first class, 9 mills if of the second class. All cities and districts may, in addition, levy a tax of from ½ to 1 mill for industrial training, and ½ to 2 mills additional for library purposes. About 85 per cent of the total expenditure for education comes from local district taxation.

**Educational Conditions** — Of the total population, about 95 per cent are white and 90 per cent are native born. The foreign born are largely English, German, and Swedish. There are few cities in the state, and about 75 per cent of the total population live in rural districts.

Since 1903 the state has had a good compulsory attendance law, and since 1905 a good child labor law. Each county is divided into from one to five truancy districts, and a truant officer is appointed to see that the law is enforced. Cities form independent truancy districts. In 1900 Kansas stood third in the percentage of literates (29 per cent) in the total population, Iowa and Nebraska alone having less. The estimated value of the school property of Kansas is \$18,000,000, or an average of about \$1900 for each schoolhouse in the state. Since 1903 the state has offered aid for industrial instruction (manual training and domestic science), duplicating any amount raised and expended up to \$250 a year in each place. Separate schools for the colored race are not permitted except in the cities of the first class and the high school at Kansas City, Kan., but a recent report of the State Superintendent recommends such change in the law as will permit of their establishment.

**Teachers and Training** — About one fourth of the teaching force each year is composed of inexperienced teachers, and about 80 per cent are teaching on second and third grade county certificates. About 5 per cent are normal graduates. For the training of these, and the improvement of those in service, a teachers' normal institute, of not less than four weeks' duration, must be held in each county each year. Adjacent counties may combine for a union institute. The time and place of holding the institute, as well as the institute conductors to be employed, must be approved by the state superintendent, and all conductors must be certificated for the work by the State Board of Education. A State Teachers' Reading Circle, under the direction of a board chosen by the county superintendents' section of the State Teachers' Association and with the State Superintendent as *ex officio* Chairman of the Board, outlines a course of reading each year for the teachers of the state, and all examinations for state teachers' certificates must include reading circle work as one of the examination subjects. For the training of new teachers, the state maintains three normal schools, and has made ex-

## KANSAS, STATE OF

tensive provision for normal training classes in the high school of the state, with annual state aid.

**Secondary Education.**—The law provides for three kinds of high schools,—district, union, and county. Cities and single districts may establish a high school for their own children, which must be maintained out of the ordinary district funds. Counties may establish county high schools for all the children of the county, by election and majority vote, and levy a special county high school tax up to six mills for the support of the same. Any two or more school districts may vote to unite to form a union for the purposes of providing higher instruction, in which case each district maintains its separate schools and the union district is a separate superimposed district, with power to levy regular district taxes, but the share paid by each district is in proportion to the number of children attending the union district. The support of all high schools is by local taxation, except that, since 1905, any county not maintaining a county high school may vote to levy a general county high school tax of from one fourth to three mills on all county property except that cities of 16,000 inhabitants or over are exempt, and to apportion the proceeds of such tax *pro rata* among the different high schools of the county in proportion to the average daily attendance in each. Pupils in non-high school districts in the poorer counties are provided with free tuition in adjacent high schools. State aid is granted for normal training classes (\$500) with \$250 additional if they also offer courses in agriculture and domestic science.

**Higher and Special Education**—The University of Kansas (*q v*), opened in 1866, and the State Agricultural College (*q v*), opened in 1863, are the two higher institutions maintained by the state. In addition to these two state institutions, eighteen denominational colleges offer higher education within the state.

## KANSAS, STATE UNIVERSITY OF

Since 1899, the state has made special appropriations for the partial support of Western University at Quindaro, an institution founded for "freedmen" before the days of emancipation. The Governor also appoints a majority of its Board of Trustees, thus virtually making it a state normal, agricultural, mechanical, and domestic science school for the colored race. The state has similarly practically adopted the Topeka Industrial and Educational Institute, a western Tuskegee, and makes small annual appropriations for its partial support. The state also maintains the Soldiers' Orphans' Home at Atchison; the State School for the Deaf at Olathe, the State School for the Blind at Kansas City, Kan., the Boys' Industrial School at Topeka, and the Kansas Industrial School for Girls at Beloit. **KANSAS, STATE UNIVERSITY OF, LAWRENCE, KAN.**—A coeducational institution forming part of the free public school system of the state, and established by act of legislature in 1864. Seventy-two sections of land had already been set apart for the purpose by Act of Congress in 1861. The institution was opened at Lawrence, the citizens of which provided the first building, in 1866. The law school was opened in 1878, the school of pharmacy in 1885, the school of engineering in 1891, in 1896 the graduate school was organized, and in 1899 a full school of medicine was instituted, in 1909 the school of education and division of university extension were added.

The government of the University is vested in a board of seven regents, six of whom are appointed by the Governor and who hold office for four years. The departments of instruction of the University are as follows: graduate, college, fine arts, law, pharmacy, medicine, summer session, education, university extension. The entrance requirements are fifteen units except in the medical school, where two years of college work are required, and in the law school, where, after 1912, one year of college work will be necessary. All the departments offer four-year courses leading to their appropriate degrees, except the law school, where only a three-year course is given leading to the LL.B. Advanced degrees, including A.M., M.S., and the Ph.D., are conferred for work in residence. The total registration in

1910-1911 was 2398. The teaching staff consists of 176 professors and 65 instructors and assistants.

**KANSAS WESLEYAN UNIVERSITY, SALINA, KAN** — A coeducational institution founded in 1886 under the auspices of the Northwest Kansas Conference of the Methodist Episcopal Church. Academic, collegiate, normal, musical, commercial, and oratorical departments are maintained. Candidates are admitted on about eight points of high school work. On completion of the appropriate courses the degrees of A. B., Ph. B., and B. S. are granted. The faculty consists of forty-three members.

**KANT, IMMANUEL** (1724-1804) — The most important and commanding figure in the development of later modern culture, and the author of the intellectual and moral revolution which brought forward and fashioned a radical conception of the significance of humanity. He was born of humble parentage in Königsberg, Germany. The advantages that came to him in youth through his education during eight years in the *Collegium Fredericianum* were due to the devotion and wisdom of his mother, the material assistance of a maternal uncle, and the belief in his ability by the family pastor, F. A. Schultz, who was also a leader in the movement known as Pietism. Despite his poverty, he completed a course at the university in his native city (1740-1746), intending, as sometimes supposed, to prepare himself for the Church. This alleged purpose waned as he passed on in the acquisition of culture in many fields under the influence of Knutzen and Teske, professors of philosophy and physics, respectively. The following nine years were passed as a tutor in several families near Königsberg, and brought to him valuable personal and pedagogical experiences.

In 1755 Kant returned to the university, and, qualifying as a private lecturer in mathematics, physics, and philosophy, was destined to pass over forty years as an eminent teacher in this one institution. His six years' service as a librarian in the castle library after 1766 enabled him to expand his acquaintance with literature in all its branches. Having earlier declined the vacant chair of poetry, he was promoted in 1770 to the professorship of logic and metaphysics. His brilliant and popular lectures covered a wide range of subjects, as was then the custom of members of the philosophical faculty. Arnoldt's inquiry into the range and repetition of Kant's lectures is in itself an interesting sketch of his versatility. He lectured on logic 54 semesters, metaphysics 49, physical geography 46, moral philosophy 28, anthropology 24, theoretical physics 20, mathematics 16, natural right 12, encyclopedia of philosophy 11, pedagogy 4, besides on a number of other subjects. He created and gave academic

standing to physical geography and anthropology, despite his lack of travel. His active teaching ceased in 1796, owing to the infirmities of age. By the exercise of strong will he overcame the physical weakness of his youth, and by regulating his daily life by principles he fashioned a character that is one of the noblest models of self-education.

Before Kant became the author of the revolutionary critical philosophy, his mental development carried him through several interesting phases. Equipped as a student with the Leibnitz-Wolffian philosophy, he turned his attention to the more scientific problems of the material universe. He held to the unity of the physical world, advocated a mechanical dynamism for the explanation of its phenomena, elaborated the nebular hypothesis to account for its origin, and gave foreshadowings of the conception of evolution (*A General Natural History and Theory of the Heavens*, 1755). These years were succeeded by a period of rather quiet and uncertain empiricism in which the influence of Hume and Rousseau seemed to impress him. The *Dreams of a Spirit-Seer explained by the Dreams of Metaphysics* (1766), was written apparently to show the impossibility of knowledge beyond experience.

In 1769 a "great light" came to him which brought out clearly the contrast between nature (to be explained by causality), and spirit (whose essence is to be found in morality and religion). In his inaugural dissertation, *On the Forms and Principles of the Sensuous and the Intellectual Worlds* (1770), he had advanced so far as to see that physical science and philosophical idealism are but two aspects of knowledge and reality which human experience unifies. In a letter to Herz (1772) there is the first definite intimation of the settling of the real problem that he tried to solve. Then followed the silent and lonely years of reflection which resulted in the *Critique of Pure Reason* (1781) and marked the beginning of the philosophical revolution that is still in progress. The new method of "criticism" shows the possibility of experience and science by discovering the *a priori* forms of space and time and the twelve categories possessed by reason, and by establishing the principle of human self-consciousness as the maker of nature and the unifier of experience. The subjective and synthetic basis of all truth of nature was made a basis for the objective and metaphysical value of morality as expressed in the "categorical imperative" of the *Critique of Practical Reason* (1788). The systematic rounding of his thinking was reached in the æsthetical and teleological principles of the *Critique of Judgment* (1790). The completeness of his attack on the problem of the unity of experience appears from the attempted harmonization of the three *Critiques* by giving a psychological foundation to the first in intellect, to the second in will, and to the third in the feelings. His service to

philosophy became a harmonization of rationalism and empiricism, of dogmatism and skepticism in the method and results of "criticism," making possible the radical development of idealistic philosophy which greeted Germany within a decade after his death.

The influence of the critical philosophy grew slowly. The less than thirty publications on it after three years grew to one hundred and fifty in five years, and fell but little short of three thousand books, pamphlets, and articles by 1804. Kant became the center of a contending mass of friends and foes. An anonymous philosophical book (by Fichte, 1794) was immediately attributed to him. Three years later Feder, who in an early review of the first *Critique* called him a Berkeleian and thus drew from Kant the *Prolegomena to Every Future Metaphysics that can appear as Science* (1783) and eventually the famous second edition of the *Critique* (1787), was on his own admission literally forced out of his chair of philosophy at Göttingen because he could not seem to understand the Königsberg philosopher. Important additional writings of Kant are *Idea of a Universal History*, etc. (1784), *Fundamental Principles of the Metaphysics of Morals* and *Metaphysical Foundations of the Natural Science* (1786), *Religion within the Limits of Mere Reason* (1793), *The Metaphysics of Ethics* (1797), *Anthropology with Reference to Pragmatic Ends* (1798), *Logic* (1800), *Physical Geography* (1802), and *On Pedagogy* (1803), the last three being edited by two of his pupils.

Kant's contributions to education as a practice and a theory are to be sought in his long career as an effective teacher of the leaders of his country, his writings bearing directly on the subject, and the immeasurable influence of his epistemological and ethical thinking upon the cultural and technical thought of his own and succeeding ages. In later years he modestly doubted the value of his early efforts as a teacher of children, saying, "there could never have been a worse tutor in the world than himself, because he could not even apply those pedagogical rules which he knew." As an academic teacher he held his chief end to be "to promote right opinions, and to inculcate fixed principles in minds of native excellence, in order to afford the only proper direction to the development of talent." His high ideal demanded that students should be taught how to think, rather than given mere information. The famous tribute of Herder in 1792 to his teacher of thirty years before shows the rare command of knowledge ("nothing worth knowing was indifferent to him"), the well-developed technique of instruction, and the effective guidance of liberty in thinking which made Kant the great teacher.

Owing to an old university rule, which required of one of the professors public lectures on the subject two hours a week, Kant's formal attention to education was given chiefly in his lectures on pedagogy throughout four semesters

between 1776 and 1787. This material, which never received systematic handling, was edited by Rink and published as *Ueber Pädagogik* (1803). It has since appeared in several German editions, and in one French and two English translations. Kant's interest in education as a topic for reflection probably awakened during the early years when Montaigne was a favorite author and Rousseau's writings riveted his attention, and continued to the end of his active career. He treated directly, however, of only a few questions in education. He drew chiefly on the memories of his own experiences as a teacher, and in part agreed with the pedagogy of the *Aufklärung* as it was expressed in Rousseau, Basedow, Campe, and others. In some of his views he characteristically departed from the positions of his contemporaries and set problems for the nineteenth century, chiefly in the evolutionary basis and the moral task of education.

Education is the greatest and hardest problem that is presented to man, because its purpose is the attainment of human destiny and perfection which consist in absolute moral worth. "Man can become man through education only." The history of the race shows progress through education toward the development of humanity. Since "there are germs in human nature" and the unfolding of "humanity from its seeds" does not take place of its own accord, education is the most necessary of all arts. A call for an effective rationalization of this art and for experimental schools is made at the same time that princes and parents are criticized for pursuing the defective aims of experience instead of "the good of the world and the perfection for which man is intended." As a principle Kant declares "Children should be educated, not with reference to their present condition, but rather with regard to a possibly improved future state of the human race, *i.e.* according to the idea of humanity and its entire destiny." His conception of education includes its necessity, its possibility, its worth, its principles, its art, and its types. It is necessary, because of the great gap existing between the rawness of infancy and the human will organized into free action under law, and because nature alone does not educate. It is possible, because a "germinal reason and a quasi-germinal morality," as innate capacities, actually equip man for perfection. It has value, because of the absolute worth of goodness as human destiny. "It is morality alone which gives meaning to man, and at the same time puts an end into educational thought and effort." It is rational and involves principles, and we may therefore hope for a future science, wherein every activity in the artistic nature of teaching will be placed on a firm basis. Education is evaluated also according to types of schools, teachers, and methods.

The educational solidarity of the individual and the race is expressed not only in his wonder

A GROUP OF GERMAN EDUCATORS.

"whether the education of the individual should imitate the development of the race in general through its various generations," but also in his insistence "that every phase of educational effort must proceed upon a recognition of the basis which natural and mechanical processes universally present, be it in physical, psychical, cultural, or moral education, in the constant endeavor to hand the child over to a free, rational, individual independence"

Kant's "treatise" on pedagogy was divided into two parts *On Physical Education* (§§ 34-90) and *On Practical Education* (§§ 91-113). The former includes all natural or mechanical processes, the latter all that has reference to freedom. The development of the individual is conceived as requiring four types of educational activity: discipline, cultivation, civilization, and moralization. Discipline includes everything pertaining to physical nature, and attempts "to prevent the animal nature from becoming injurious to human nature," both individually and socially. Under cultivation are included instruction and teaching, which are designed to equip the individual with skillfulness as the means of executing a great variety of purposes. Civilization, which is not treated by Kant, leads to the acquisition of prudence, and the complete socialization of the individual. Moralization is the means of bringing the individual to "acquire that type of mind which chooses good aims only." He charged his age with developing the first three and omitting the fourth type of educational activity.

The antinomy between constraint and freedom haunted Kant constantly. He returns repeatedly to the question "How shall I cultivate freedom under conditions of compulsion?" His only definite recommendation with respect to the plan of instruction was the introduction of "a catechism of right," an outline of which he furnishes in the *Metaphysical Elements of Ethics* (1797). The method proposed invites children to apply the moral law to concrete cases of conduct, and thus become conscious of it and accept it as the one obligatory principle of the will. Moral education differs in aim and in method from the cultural development of the mental capacities of the individual. The ethical conception of duty also became the basis for religious pedagogy. His insistence on freedom as the essence of man's intelligible character and the very opposite of causality as the key to empirical character greatly influenced the educational theory of the following century, as is instanced in Herbart's polemic against transcendental freedom, and its continuance by his followers.

Kant disapproved of a state scheme of education, because it was too narrow and misdirected. The development of humanity being the end of education, "the basis of its plan must be cosmopolitan". Princes also distort education by seeking merely to make men "citizens" who are to be used to further the immediate

purposes of the State. His great interest in Basedow's philanthropic institute at Dessau was therefore due to his belief in this experiment as promising a way of true educational reform.

The philosophy created by Kant was itself a system full of pedagogical motifs by reason of its acute analysis of inner experience and its recognition of the creative power of pure reason. It also became fruitful in opening the current epoch of western thought in which the pedagogy as well as the philosophy of Fichte, Schelling, Hegel, Schopenhauer, Herbart, Schleiermacher, Schuller, Goethe, Niemeyer, Schwarz, and their numerous followers radiated throughout the nineteenth century. E. F. B.

**KAY-SHUTTLEWORTH, SIR JAMES PHILLIPS** (1804-1877) — First Secretary of the Committee of Council on Education in England and Wales, was born at Rochdale, Lancashire, in 1804, the son of Robert Kay. As a boy he was employed in a bank belonging to a relation at Rochdale, but in 1824 entered the University of Edinburgh as a student of medicine, becoming M.D. 1827. He had a brilliant university course during which, both in Edinburgh and in Dublin, he studied the condition of the poor. After graduating he settled at Manchester as a physician and served as medical officer of the Ancoats and Ardwick Dispensary situated in one of the poorest and most crowded districts of the city. During the outbreak of cholera in 1832 he was devoted in his attendance at the cholera hospital. The experience gained during this epidemic and as secretary to the Manchester Board of Health impressed upon him the social danger of the insanitary surroundings of the poor. In 1832 he published a pamphlet entitled *The Moral and Physical Condition of the Working Classes Employed in the Cotton Manufacture in Manchester*, the disclosures of which led to

local measures for sanitary and educational reform. He was an ardent supporter of the Anti-corn Law movement. He was appointed in 1835 Assistant Poor Law Commissioner, and for some years served in that capacity first in Norfolk and Suffolk and afterwards in the metropolitan district. As a Poor Law official he became more than ever convinced of the necessity of national educational reform. In 1839, when the Committee of the Privy Council for Education in England and Wales was first appointed, in order to administer the parliamentary grant for public education in Great Britain, Dr Kay (as he was then called) was appointed the first secretary of the Committee, being allowed to retain for a time the superintendence of the metropolitan schools for pauper children under the Poor Law Board. He thus became the first secretary of the Education Department for England and Wales.

Hand in hand with his intimate friend and colleague under the Poor Law Board, Mr. Edward Carleton Tufnell (born at Chichester 1806, educated at Eton and Balliol College, Oxford, and subsequently director of Greenwich Hospital), Dr Kay worked out a plan for establishing a training college for the preparation of teachers who would devote their lives to the care of hapless pauper children in the Poor Law Schools of Norwood. The condition of these children was deplorable. Kay and Tufnell conceived the idea of establishing a training college, the discipline and spirit of which should fit and inspire young men for this task of mercy and rescue. Their first step was to travel in Europe in order to acquaint themselves with the best that had been done in other countries for the professional training of teachers destined for the schools of the poor. After visiting Holland, Prussia, and France they went into Switzerland, attracted by what they had heard of the work of Pestalozzi (who had died in 1827) and of Fellenberg and Father Girard (*qqv*) who were still engaged in their educational work. Returning to England, Kay and Tufnell found premises at Battersea in West London. The house still forms the nucleus of St John's College, Battersea. In 1840 the college was opened for the admission of students, the first pupils being some boys selected from the school of industry at Norwood in view of the excellence of their conduct and their intellectual promise. The period of instruction in the training school was to last for three years and to be followed by two years' employment as pupil teachers in the Battersea village school during three hours of every day. The new training college, which was maintained at the private cost of Kay and Tufnell, was cordially supported by philanthropists in all parts of the country and quickly grew into an institution of considerable size. The whole of the household work was committed to the charge of the boys and young men. The masters

partook the same diet as the pupils. The aim was that the teacher of the peasant's child should himself be acquainted with the peasant's duties. In this, the first organized training college for men teachers in England, the first Secretary of the Education Department resided during the critical years in which he built up the administrative fabric of English public education under the supervision of the civil State.

The success of the college was great. In 1843 Kay (who had assumed the name of Kay-Shuttleworth on his marriage in 1842 with Janet, daughter and heiress of Robert Shuttleworth of Gawthorpe Hall, near Burnley) handed over the college to the committee of the National Society (*qv*), by whom it has been conducted with increasing usefulness, though with great modifications in its curriculum and mode of life, to the present day.

In the meantime Kay-Shuttleworth had thrown himself with vigor into the new work of the Education Department. On his appointment as Secretary, the Ministers of the Crown had given him a special injunction to assert the civil influence in education. The first steps were to propose (1) the establishment of a great training college for teachers, and (2) the inspection of all schools receiving government aid. The first of these schemes was wrecked by dissensions between the civil power and the ecclesiastical bodies on the subject of the religious instruction to be given in the college. The second part of the plan, viz. inspection, was entirely successful, the whole weight of the Benthamite tradition favoring the adoption of the plan. It was because the idea of a state training college broke down that Kay-Shuttleworth and his friend Tufnell determined to establish the training college at Battersea at their own expense. Their indomitable courage and personal self-sacrifice won the day. Established by private effort, the college became the first of a long succession of training institutions.

During the early years of his secretaryship, Kay-Shuttleworth proved himself brilliantly resourceful in administrative ideas. He persuaded the government to employ John Hullah to introduce a modification of the Wilhelm method (the fixed *doh* system) into the teaching of singing in elementary schools. It was an application of the Pestalozzian method of ascending from the simple to the general through a clearly analyzed series of steps. Hullah's efforts were extraordinarily successful. Kay-Shuttleworth also introduced Pestalozzian methods of the teaching of arithmetic and geography. He was also the first to insist upon the teaching of drawing as an indispensable part of elementary education.

In 1843 the Committee of Council, on Kay-Shuttleworth's advice, began to give regular grants in aid of (1) the erection of teachers' residences; (2) the purchase of school furniture and apparatus; and (3) the establishment of training colleges under the management of

religious bodies or approved educational societies. This gave a decisive turn to English policy in regard to national education. The idea of a State monopoly in elementary education was definitely abandoned. Under Kay-Shuttleworth's influence the State entered into a partnership with the religious and voluntary associations for the improvement of the education of the poor. This concordat between the civil state and the religious or voluntary associations was the keynote of Kay-Shuttleworth's policy. In an eloquent pamphlet entitled *The School in its Relations to the State, the Church, and the Congregation*, issued anonymously with the sanction of the government, Kay-Shuttleworth expounded the policy of the new Minutes and vigorously defended the idea of a concordat between the State and the religious bodies against the secularist party on the one hand and the anti-governmental ecclesiastical writers on the other.

Owing to a breakdown of health from overwork, Kay-Shuttleworth resigned his office of Secretary of the Committee of Council in 1849. In the same year he was created a baronet. Recovering from his illness he devoted himself with ardor to public work. He was vice-chairman of the Central Relief Committee during the cotton famine in Lancashire, 1861-1865. He served on the Royal Commission on Scientific Instruction (Duke of Devonshire, chairman) from 1870-1873. His later years were occupied with reforming the administration of several local grammar schools, especially Giggleswick and Burnley. He died in London, 1877.

Kay-Shuttleworth was the true begetter of the modern English system of elementary education aided by the State. The training of teachers, public inspection of schools, the pupil teacher system, the combination of secular instruction with religious teaching and with liberty of conscience, and the synthesis of contributions from the government treasury and from local benefactors were prominent features of his plan, and all of them have persisted with modifications down to the present time. Matthew Arnold said with justice that, "when at last the system of English elementary education comes to stand fully and fairly formed, Kay-Shuttleworth will have a statue." He combined in his own person the administrative decision of the Benthamites, the philanthropic ardor of the sanitary reformer and the religious zeal of the Anglican statesman.

**KEATE, JOHN** (1773-1852) -- Headmaster of Eton College from 1809-1834. He was educated at Eton and King's College, Cambridge, where he distinguished himself in classical scholarship. He graduated B.A. in 1796 and was elected fellow. In 1791 he was appointed assistant master at Eton and in 1809 became headmaster. His whole career was a struggle with the frequently turbulent and rebellious boys; discipline was bad, and he suffered many indignities. Under such conditions the state of scholarship was poor. Keate's chief claim to fame as headmaster was his constant and wholesale use of the birch, on one occasion he flogged as many as eighty boys. Many stories are related of the flogging headmaster. He distrusted boys as much as Hawtrey and Arnold (*qq v*) relied on their sense of honor. Nor was the staff of masters of the standard of scholarship usually connected with good schools. In the end, however, Keate attained a measure of popularity and secured efficient assistants. He was able on his resignation to hand over to his successor, Hawtrey (*q v*), a better disciplined school than he had found. He sympathized with educational reforms, but the problem of discipline absorbed the greater part of his attention. He did encourage oratory and English composition and the establishment of debating and other societies. After his resignation he lived in retirement as rector of a country church.

**KEBLE, JOHN** (1792–1866). — English poet and divine, born at Fairford, Gloucestershire, the son of a clergyman from whom he received his education until his entry into Corpus Christi College, Oxford. He obtained a fellowship at the early age of nineteen, after graduating with a double first. He was ordained in 1815 and remained at Oxford until 1823, when he became a parish priest. In 1827 he published the *Christian Year*, a collection of religious poems which attained a remarkable popularity. From 1831–1864 he was professor of Poetry at Oxford. In 1835 he became Vicar of Hursley in Hampshire. It is, however, with the “Oxford Movement” that Keble is most generally identified as one of its chief leaders and inspirers. Connected with this movement were his share in the *Tracts for the Times* and the translation of the Church Fathers (*Library of the Fathers*). Keble wrote many books on religious topics and in addition to the *Christian Year* was the author of *Lyra Innocentium* (1846), and *Prælectiones Academicæ* (1844), in which he discussed the theory of poetry. On state control of schools, which was suggested in his day, Keble took the stand that England “as a Christian nation was a part of Christ’s Church and bound in all her legislation and policy by the fundamental laws of that Church.” Keble College, Oxford, opened in 1870, was named in honor of Keble, “to the memory of one of the most eminent and religious writers whom the Church of England has ever produced, one whose holy example was perhaps even a greater power for good than his *Christian Year*.”

See OXFORD MOVEMENT.

**KEHR, KARL** (1830–1885). — A German educator, born in Goldbach, Thuringia, and educated at the seminary at Gotha, where he was appointed teacher of pedagogy in 1863. In 1872 he became the director of the seminary, which position he later exchanged for a similar one at Halberstadt, and finally at Erfurt. Through his efforts in these positions, as well as through his numerous writings, he exerted a great influence on the training of teachers in Germany. His most important work is his *History of the Methods of Elementary Instruction in Germany* (*Geschichte der Methodik des deutschen Volksschulunterrichts*), published with the collaboration of a number of schoolmen in 1877. He was the founder of *Padagogische Blätter für Lehrerbildung und Lehrerbildungsanstalten*.

**KEILHAU**. — A village near Rudolstadt in Thuringia, Germany, the scene of Froebel’s first school, which he established in 1816 for the education of his brother’s children and others. Although founded in Griesheim as the *Allgemeine deutsche Erziehungsanstalt*, it was soon moved to Keilhau. Froebel was assisted by Wilhelm Middendorff and Heinrich Lange-thal; in 1823 they were joined by Johannes Arnold Barop, a nephew of Middendorff. Froebel left the institution in 1829. Under the influence of Barop, who became sole owner of the school in 1854, the institution gradually developed into a private boarding and secondary school. In 1870 the examination for the one year military service was held in the school for the first time. In 1878 Barop died and was succeeded by his son, Johannes Barop. In 1892 the Prussian curriculum for secondary schools was introduced, but the principles of Pestalozzi and Froebel remained, and the institution is still marked by the emphasis on the social and cooperative work. The school is now a Realschule with Latin as an optional subject. There are about 100 pupils. In 1896 an alumni association was formed. The present headmaster is Dr. Otto Wachter.

**KELLER, JOSEPH EDWARD** (1827–1886). — Jesuit educator, educated at St. Louis University. He held professorships at St. Francis Xavier’s College, Cincinnati, and St. Joseph’s College, Bardonia, Conn. He was president of Woodstock College and provincial of St. Louis University. He was author of several religious and philosophical works.

W. S. M.

**KELLNER, LORENZ** (1811–1892). — One of the most prominent Catholic schoolmen of modern Germany, born at Kalteneber, near Heiligenstadt, Prussia, and educated at the seminary of Magdeburg. After a few years’ experience as an elementary teacher, he was appointed to a position in the newly founded seminary at Heiligenstadt, of which his father was the principal. From there he was called, in 1848, as school inspector to Marienwerder, West Prussia, and later on in the same capacity to Trier in the Rhine province, where he worked for thirty-one years until his retirement in 1886. For several years he was a member of the Prussian parliament. He published a large number of educational works and articles treating of the history of education, the methods of teaching the mother tongue, and other matters of pedagogical interest. Among these may be mentioned: *Erziehungsgeschichte in*

*Skizzen und Bildern; Zur Pädagogik der Schule und des Hauses*, etc His autobiography, *Lebensblätter, Erinnerungen aus der Schulwelt*, is a model of its kind F M

**KENDRICK, ASAHCL CLARK** (1809-1895). — College professor and textbook author; graduated from Hamilton College in 1830, and later studied at the University of Athens He was tutor and professor at Colgate University from 1831 to 1850, and professor at the University of Rochester from 1850 to 1880 His published works include *Child's Book in Greek, Introduction to Greek, and Greek Grammar*; he also edited several of the Greek classics W. S. M.

**KENESIS.** — See TROPISM

**KENNEDY, BENJAMIN HALL** (1804-1889). — One of the most brilliant classical scholars in England during the last century and headmaster of Shrewsbury School He belonged to a family of distinguished scholars When he entered Shrewsbury School in 1819, he at once attracted attention by the remarkable quality of his compositions, and while still at school he won the Porson Prize, one of the most important of the classical prizes at Cambridge University In 1823 he entered St John's College, Cambridge, and graduated B A with great distinction After serving for a year as assistant master at his old school he was elected to a fellowship at his college in 1828 From 1830-1835 he was assistant master at Harrow and in 1836 he was elected headmaster of Shrewsbury. Here his first task was to reduce the school to discipline, which, as in most English public schools of the day, was somewhat lax. He also paid much attention to the housing accommodations, then in a very bad state through overcrowding While laying chief stress on the classical studies, he introduced French and mathe-

matics, geography and history into the curriculum, although little value was attached to any of these subjects and none counted for promotion Another innovation was the institution of daily supervised preparation, athletics were encouraged, religious instruction and devotion were strengthened, and the establishment of a school choir encouraged an interest in music. In many ways Kennedy's reforms show the strong influence of Arnold (*qv*) at the neighboring school at Rugby When the inhabitants of Shrewsbury claimed that the school was founded as a free school in the literal sense, Kennedy wrote a pamphlet, *Shrewsbury School, Past and Present* (1862), to prove that *Libera Schola Grammaticalis* meant a royally chartered school preparatory for the universities, a view which was proved to be baseless (See FREE SCHOOLS) Kennedy was not only a remarkable classical scholar, but widely read in modern literature and history As a teacher he was, in spite of his impulsiveness, eminently successful, and trained a large number of famous scholars He had a remarkable ability in writing Latin verse, as may be seen in *Sabrina Corolla* (1850) and in *Between Whiles, or Wayside Amusements of a Working Life* (1882) His influence on classical teaching was exercised by his grammars, especially the *Public School Latin Primer* (1866) and the *Public School Latin Primer* (1871), he also edited a number of classical texts, including Vergil, the *Agamemnon* of Aeschylus, and Sophocles' *Edipus Tyrannus* He resigned from the headmastership in 1866, and in the following year was appointed Regius Professor of Greek at Cambridge.

**KENTUCKY, STATE OF** — Originally a part of Virginia, organized as a separate territory in 1790, and admitted as the second new state in 1792 It belongs to the South Central Division, and has a land area of 40,000 square miles In area it is practically the same size as Ohio or Virginia For administrative purposes the state is divided into 119 counties, and these in turn into cities and towns on the one hand, and into educational subdivisions and subdistricts on the other In 1910 Kentucky had a population of 2,289,905, and a density of population of 57 per square mile

**Educational History** — The first permanent settlement was made in 1774, and the first private school was opened at Harrodsburg in 1776 Other schools were opened, and private higher schools or academies were established at various places before 1800, but these schools were very primitive and elementary In 1799 the foundation of a state university, to be known as Transylvania University, was laid by the union of Transylvania Seminary, estab-

lished by Virginia in 1780, and Kentucky Academy, chartered by the Kentucky legislature in 1794. The institution for a long time remained but little more than an academy. Though a number of private and advanced schools existed in the different settlements, no general interest in education existed before 1820 at least. So far as there was any interest, it centered about the academies, but even they did not prosper, and their lands and funds were not infrequently mismanaged or squandered. The state constitution, adopted at the time of admission, and a second state constitution, adopted in 1799, contained no mention of education.

The first legislation with reference to education took place in 1798, when the legislature granted 6000 acres of land to each of three academies and two seminaries. In 1805 and 1808 acts were passed extending these provisions to all the existing counties. Permission to raise \$1000 by a lottery was also given to each institution. By 1820 there were forty-seven county academies in operation, though they led but a precarious existence, and their failure as a system of education began to be recognized by this time. Between 1819 and 1829 six colleges were chartered, which were destined to compete with and eventually to ruin the chances of Transylvania University developing into a strong university.

The first mention of education in a message of the Governor occurs in the messages of Governor Slaughter in 1816, and again in 1817, 1818, and 1819, but the legislature took no action on his recommendations. In December, 1821, the state made provision for the first aid for common schools by providing that one half of the net profits of the Bank of the Commonwealth were to be set apart to form a permanent Literary Fund, but the income, which eventually amounted to about \$60,000 a year, was not spent for education, but was used by the legislature for defraying deficiencies in the general state revenues. In 1821 the legislature was induced to appoint a commission to investigate the question of public education and to make a report on the subject. This the commission did in 1822, reporting in favor of fostering Transylvania University as a state institution, the retention of the academies as training schools for teachers, and the establishment of a general system of public education for all, as nearly free as possible. The report favored the New York plan, with state appropriations supplemented by local taxation. The document was an able one, but since the people were not ready for taxation for education, the legislature did nothing more than print the report.

Louisville had the best schools in the state at the time, and in 1829 these were made free schools by a city appropriation for support. The next year, however, the city reverted to tuition fees, which continued up to 1840, when

the schools were once more made free city schools. Night schools were established in 1834, and a superintendent of schools was first appointed in 1839.

An act to establish "a uniform system of public schools" was passed in 1830. This gave county courts power to lay off the counties into school districts, and the people were to elect three trustees for each district. Taxes up to six and a quarter cents on the \$100 and a poll tax of fifty cents might then be levied for schools. So small was the interest in education, and so great the unwillingness of the people to pay taxes for schools, that few schools were ever organized, and the law remained practically a dead letter. The distribution of the surplus revenue in 1837 seems to have awakened a new interest in education. By an act of 1838 \$850,000 of this fund was set aside for education, and the foundation of a public school system was laid. By this law a state school fund was established; a state board of education and a state superintendent of common schools were created; and county school commissioners, district school trustees, and local taxation were provided for. At this time, half of the children of school age had never been to school, and one third of the adult population could not read or write. This law provided a definite form of organization, but it took fifteen years to overcome the indifference and the opposition of the legislature and the people sufficiently to get the law into operation in every county, and no marked progress was made until after the Civil War. In 1840 the state refused to pay the interest on the school fund, and in 1845 the state school bonds were destroyed by legislative act. In 1848 the debt to the school fund was recognized and capitalized in the form of a bond; and in 1849 a proposal to levy a state two cent tax for schools was submitted to a vote of the people and adopted. The new constitution of 1850, the first to mention education, contained a section which fixed the debt of the State to the school fund and declared it to be inviolate for the purpose of sustaining a system of common schools, and another section which provided for the election of a state superintendent of public instruction. In 1850 a law declaring the debt to the school fund a first charge on the resources of the treasury was carried in spite of the determined opposition of the Governor, and in 1853 some kind of a school was finally got into operation in each county of the state. The yearly income from all state sources was at this time but sixty cents per census child. By 1863 the income had risen to \$1.10, but the losses of the Civil War caused it to fall to seventy-two cents by 1867. In 1855 the state school tax was raised from two cents to five cents by popular vote, and in 1856 an unsuccessful attempt to revive Transylvania University by converting it into a state normal school was made. The Civil War for a time seriously interrupted the

work of education, and at its close the need of educating the negro was added to the educational problems of the State.

In 1867 agitation for a better organized and financed system of public education was begun by the new State Superintendent, Z. F. Smith. Two years later his proposals for an increase of the state school tax from five cents to twenty cents, with poll taxes and local taxation, were approved by the legislature and the people, and in 1870, a new school law was enacted which laid the basis of the present system. In 1873 district taxation was authorized to supplement the state funds. A system of colored schools was begun in 1866, when all taxes paid by the colored people were set apart for the benefit of colored schools, and in 1882 the apportionments for white and colored schools were equalized, and the state school tax raised from twenty cents to twenty-two cents. Since this time other additions have been voted, the present tax being twenty-six and a half cents. In 1884 county superintendents, elected by the people, were substituted for the county commissioners appointed by the county courts, the size of districts reduced, and provision made for state and county institutes.

In 1891 another new constitution was adopted, in which full and definite provision for a state system of public instruction was made for the first time, and the legislature was charged with the duty of providing "an efficient system of common schools throughout the state." The school fund was carefully defined, the direct-tax refund made by the national government, amounting to \$606,641.03, was added to the permanent fund, separate schools for the two races were made mandatory, the income from the fund was required to be distributed without distinction as to race or color; and aid to sectarian schools was forbidden. The revised school law of 1893 carried these provisions into effect and provided, in addition, for the grading of all schools a five-months term, obligatory county teachers' associations, and county teachers' libraries. In 1896 a compulsory school law was enacted, which required eight weeks of continuous attendance each year from all children between seven and fourteen. In 1902 an act providing for county taxation and a county poll tax to extend school terms was enacted. In 1904 county school book commissioners to select a series of uniform textbooks for the schools of the state were provided for. In 1906 two state normal schools for white teachers were established. In 1908 a county school district law was enacted which provided for a partial abandonment of the school district plan and a partial approach to the county unit system. County high schools were also provided for. An educational commission was also created for the purpose of considering a revision and improvement of the school laws of the state.

**Present Educational System.**—At the head of the state school system is a Superintendent of Public Instruction, elected by the people for a four-year term and receiving an annual salary of \$2500. He prepares all blanks and registers used, issues plans for school buildings; renders decisions on appeal; is general custodian of the school funds; must travel and visit the schools of the state; apportions the state school fund; makes plans for the teachers' institutes, and holds an annual conference with the institute conductors. He is also a member *ex officio* and chairman of the State Board of Education, the State Board of Examiners, and the Boards of Trustees of the three state normal schools, and a member *ex officio* and secretary of the State School Book Commission.

The State Board of Education is an *ex officio* body, consisting of the State Superintendent of Public Instruction, the Secretary of State, and the Attorney-General. It has charge of the school fund bonds, makes rules and regulations for the government of schools and the management of county teachers' libraries, and prescribes and publishes a graded course of study for use in the schools. The State Board of Education, together with the Governor, Auditor, Treasurer, and Clerk of the Court of Appeals, form the State School Book Commission, which adopts a series of textbooks for the schools of the state, acting on the recommendation of the different county school book commissions. The Superintendent of Public Instruction, together with two professional educators appointed by himself, constitute the State Board of Examiners. This body examines all county superintendents and all applicants for state diplomas and certificates, and prepares, subject to the approval of the State Board of Education, all questions used in the state and county examinations of teachers.

For each county a county superintendent of public instruction is elected by popular election for four-year terms. He must hold or secure a state certificate or diploma or a county superintendent's certificate. He must visit the schools of his county, superintend the taking of the annual school census and examine and report the results, decide all questions touching the administrative duty of teachers or trustees, pay all teachers on the certificates of the trustees, requisition the county judge for all textbooks needed to supply to indigents, and make an annual settlement with the county judge and an annual report to the State Superintendent. The county judge makes appointments, and may remove the superintendent for cause. With the county judge or the county attorney, he divides the county into districts and groups these into four, six, or eight subdivisions. Each district then elects one trustee and the different trustees unite to form subdivision boards of trustees, of each of which the county superintendent is *ex officio* a member, but without a vote except in case

of a tie. The chairman of these subdivision boards of trustees, together with the county superintendent, form the county board of education for the county. This body grants all county teachers' certificates, and the county superintendent makes a report of all receipts and expenditures to it. It employs all teachers for the county high schools and fixes their salaries, and may prescribe a course of study for the same. It determines the amount of county school tax needed and lays the amount before the financial court of the county. It may establish new school districts, change boundaries, and consolidate districts. It holds the title to all school property, and may condemn or purchase sites and build and repair school buildings. County boards are required to establish at least one county high school in each county not having a four-years high school, or to unite with such a school already in existence, and to arrange for the free tuition of all high school pupils in the county. Three and two year high schools may also be provided, and all courses shall include domestic science, manual training, and elementary agriculture. The county superintendent, together with two persons appointed by him, constitute the county board of examiners. This body examines all candidates for county teachers' certificates, using uniform state questions, and reports the results to the county board of education. The county superintendent, together with the county judge and the county attorney, constitute a county school book commission, of which the county superintendent is chairman. This body meets, examines the books submitted to the State School Book Commission in response to its advertisement and reports its choice. A book to be adopted must receive a majority vote of the county school book commissions, except that after three trials, the books having the largest number of votes may be adopted.

The school district law is an attempt on the part of the state to do away with some of the evils of the district form of school government, and is an approach toward the county form of school government. The number of trustees for each school district has been reduced to one, holding office for two years, and he is a member of a subdivision board of trustees. Each trustee is required to supervise the school or schools of his subdistrict, compile an annual school census, and report in writing to his division board. The division boards elect the teachers for the different schools, and have general oversight of the schools. Graded school districts, levying a special school tax for graded schools, may be established by petition and affirmative vote of the people. Such districts may elect their own boards of trustees, who possess about the same powers as boards of trustees for county subdivisions, and who report to the county superintendent of schools. Cities similarly enjoy special privileges, and

report to the State Superintendent direct. Graded school districts and cities receive their quota from the state school fund, but are exempt from the county school tax levied, if they levy a local tax of twenty cents for schools. The colored race may establish graded schools on the same terms as the white race, that is, each race pays for its own. Money and taxes for ungraded common schools are distributed without reference to race or color.

**School Support** — The State was admitted before the policy of making land grants for education was begun by the national government and hence received no public land for schools. The permanent school fund of the state is largely nominal, being in the form of bonds of the commonwealth, the interest on which is raised, in part, by direct taxation. The state money is apportioned to the counties (for the districts) and cities on the basis of the number of census children, six to twenty years of age, though in making the apportionment, no subdistrict is considered as having less than fifty census children. A county school tax of not over twenty cents on the \$100 and a county poll tax of \$1 may also be levied by the fiscal courts of the county, on the recommendation of the county board of education, but all cities and special tax districts which levy a local tax of twenty cents are exempt from this so-called county tax. Any subdistrict may levy a local tax up to twenty-five cents, but very few do. Graded school districts, where established by either race, may levy a local tax up to fifty cents and a local poll tax up to \$1.50. County high schools are maintained out of the county school tax.

**Educational Conditions.** — Of the total population about 87 per cent are white and 13 per cent are negroes. Only about 3 per cent of the population are of foreign birth. The state is largely rural and agricultural, 78.2 per cent of the total population living in rural districts, and about 18 per cent living in cities of over 8000 inhabitants. The illiteracy in the state in 1900 was very large, 16.5 per cent of the total population over ten years of age being illiterate. The percentage of illiterates among the whites was 12.8 per cent and among the colored people it was 40.1 per cent. This has been materially reduced since 1900.

In material conditions, the schools of the state, outside of the cities, make little better showing. Schoolhouses and school repairs are still provided largely by local subscription, though the number built by voting bonds has increased within recent years. As late as 1907 11.5 per cent of the schoolhouses of the state were log houses, and but 1.5 per cent were of brick or stone. Only 77 per cent of the schoolhouses are reported as being supplied with suitable desks and blackboards; 41 per cent as being supplied with globes, maps, and charts; while the average value of furniture and apparatus was but \$57 per schoolhouse, and the

## KENTUCKY, STATE OF

average value of schoolhouses and grounds was \$365 each. In the twenty-five cities of the state good school buildings are provided.

The school system of the state is as yet imperfectly organized, and the elementary school system is only imperfectly developed. The establishment of graded schools will help to round out the elementary school work, though these can be organized only in the more thickly populated districts, and few can be organized for the negro race under the present laws. In 1906-1907 there were 165 white and thirteen colored graded schools in the state. No statistics as to length of term of the county schools are available, other than that only 8 per cent of the schools are maintained for more than six months. No statistics are available to show the number of teachers who have had any form of professional training, but the number is not large.

**Teachers and Training** — Up to 1906 the preparation of white teachers for the state was made in private institutions, but in that year two state normal schools for white teachers, the eastern and the western state normal schools, were established by the legislature, and both of these have done good work during the short time they have been in existence. For the education of colored teachers the state has for some time maintained the Kentucky Normal and Industrial Institute for colored persons, an institution offering normal, agricultural, mechanical, and domestic instruction.

**Secondary and Higher Education** — Graded schools have been organized in many of the towns, but a high school system for the state is only now in the process of development. The new high school law of 1908 provides that the county boards of education, by 1910, must establish one or more county high schools in each county not having a first-class (four-year) high school, and directs the county boards to provide for the free tuition of all pupils completing the course of study in the elementary schools of the county. The law provides for the establishment of two, three, and four year high schools, and provides that domestic science, manual training, and elementary agriculture shall form a part of all high school courses of study. The funds for providing these schools are rather meager, as all county boards of education are allowed to levy a county school tax of only twenty cents on the \$100 for all purposes, and out of this fund the high schools must be maintained. With the awakening of the state in all matters relating to education which is now under way, a good system of secondary schools may be expected to be developed before long.

In higher education the state helps to maintain the State College of Kentucky (*qr*), located at Lexington. This institution owes its origin to the Land Grants of 1862, the institution opening in 1866. In 1880 a state tax of one cent was imposed for the benefit of the

## KENTUCKY WESLEYAN COLLEGE

college, and in 1904 an additional appropriation of \$15,000 per annum was made. The institution is a combined agricultural and mechanical college and a school of science and arts. The state also maintains the Kentucky Normal Industrial Institute for Colored Persons, located at Frankfort; two normal schools for white teachers, the Kentucky Institute for Feeble-minded Children at Frankfort, the Kentucky School for the Deaf at Danville, and the Kentucky Institution for the Education of the Blind at Louisville. Ten colleges for men or for both sexes, and nine for women, mostly denominational, supplement the one state institution in providing collegiate instruction for the young people of the state.

**KENTUCKY, STATE UNIVERSITY OF, LEXINGTON, KY.** — A coeducational institution founded in 1865 as a Land Grant college as a constituent member of Kentucky, now Transylvania, University. In 1878 the agricultural and mechanical college was separated from the university and in 1880 was moved to Lexington. By an act of the General Assembly the style and title of the institution was changed to State University. At present provision is made for departments of agriculture, mechanic arts, and military science; an experiment station is maintained; and instruction is offered in sciences and classics. The entrance requirements are about fifteen units. The university embraces an academy, colleges of arts and science, agriculture, civil, mechanical, and electrical engineering, law, and a school of education. The college of law, to which after 1911 only candidates who can be admitted to the freshman year of college work will be admitted, gives a three-year course leading to the degree of LL. B. The School of Education courses are accepted by the state for teachers' certificates of different grades and duration. There were enrolled in 1909-1910, 721 students, of whom 427 were collegiate, 46 law, and 155 in the academy. The faculty consists of 65 members.

**KENTUCKY WESLEYAN COLLEGE, WINCHESTER, KY.** — A coeducational institution founded in 1863 and under the auspices of the Kentucky Conference, Methodist Episcopal Church, South. It provides preparatory and collegiate courses. The requirements for admission are fifteen points of high school work. Courses are offered leading to the A. B. and B. S. degrees. The A. M. degree is conferred after a year's work in resi-

dence and the presentation of a thesis. The faculty consists of nine professors.

### KENYON COLLEGE, GAMBIER, OHIO.

— Founded in 1824 as the theological seminary of the Protestant Episcopal Church in the diocese of Ohio. The present title was adopted in 1891. Candidates are admitted by certificate from high schools or by examination, the requirements being fifteen units. The college courses are divided into four groups, the classical course leading to the A B degree, the philosophical course leading to the Ph B degree; the scientific leading to the B S and the literary leading to the B L. The faculty consists of twenty members.

**KEPLER, JOHN** (1571–1630) — One of the great astronomers, born at Weil in Wurttemberg. After attending various schools, he entered the University of Tübingen and studied classics and theology. He found an opportunity to study the Copernican system privately and devoted himself to the subject. In 1594 he was appointed to the chair of mathematics at Gratz, and had sufficient time to pursue his astronomical studies. In 1600 he became Tycho Brahe's laboratory assistant and in 1601 succeeded his master as imperial mathematician and astronomer. His first work which attracted attention was the *Mysterium Cosmographicum* (1596). In 1609 he published *Commentaries on the Motions of Mars*, the study of which had been assigned to him by Tycho Brahe. In this work he established two important rules: (1) of the elliptical movement of planets, (2) that the line joining the planet to the sun sweeps out equal areas in any two equal intervals of time. In 1612 Kepler became a teacher at Linz and continued his investigations. Between 1618 and 1621 he published: (1) *Epitome of the Copernican Astronomy*, in which his two previous laws are applied to other planets besides Mars, the distance from the earth to the sun is given with greater accuracy than by previous writers, the eclipses of the sun and moon are discussed and explained. (2) *Harmony of the World*, in which he formulated his third important rule that "The squares of the times of revolution of any two planets (including the earth) about the sun are proportional to the cubes of their mean distances from the sun." It was also in this book that he discussed the "music of the spheres," and gave a musical notation for each of the planets. (3) *Comets*, which included an account of the comet later known as Halley's Comet. In 1627 he published the *Rudolphine Tables* which were based on the observations made by Tycho Brahe and himself. While Kepler is ranked among the leading astronomers, much of what he wrote is of little value; of a mystical temperament, he often gave himself up to wild speculations, allegorical interpre-

tations, and astrological explanations and predictions. On the whole, however, his method of work was scientific, for however fanciful his hypotheses may have been, he was untiring in correcting these by thorough observation and investigation.

**KERLIN, ISAAC N** (1834–1893) — Educator of feeble-minded and backward children. He was educated in the schools of New Jersey and the University of Pennsylvania, taking a medical degree in the latter institution in 1856. He engaged in teaching feeble-minded children, and from 1858 to 1892 he was superintendent of the Pennsylvania School for Feeble-minded Children. He was the author of a number of papers on the care and training of feeble-minded and idiotic children. W. S. M.

See FEEBLE-MINDEDNESS

**KERSEY, JOHN** (1616–1690?) — Teacher of, and writer on, mathematics. In 1650 he was teaching in Covent Garden, London, and afterwards he removed to the Sign of the Globe in Chandos Street, St. Martin's Lane, London. In 1650 he published *Arithmetique Made Easie, or a Perfect Methode for the true knowledge and practice of Natural Arithmetique, according to the ancient vulgar way, without dependence upon any other Author for the grounds thereof*. By Edm. Wingate, Esquire. *The Second Edition, Enlarged (at the request and with the approbation of the Author with divers chapters)*. By John Kersey, Teacher of the *Mathematiques*. The late Professor Augustus de Morgan described Wingate as "one of the very best of the old writers on arithmetic." Kersey is also associated with Edward Cocker's *Decimal Arithmetic*, 1684. On the title page it is stated "Whereunto is added also his Algebraical Arithmetic according to the Method used by Mr John Kersey in his Incomparable Treatise of Algebra." This had been published, the first volume in 1673 and the second in 1674, as *The Elements of the Mathematical Art, commonly called Algebra*. This work received the commendation of some of the best mathematicians, and became for some time the standard work. The Prospectus of John Kersey, which appears in the 1650 edition of Wingate's *Arithmetic*, shows the mathematical teaching in probably the best mathematical school of the times. F. W.

**KEUKA COLLEGE, KEUKA PARK, N Y**

— A coeducational institution chartered in 1892 as a member of the University of the State of New York. The first class was graduated in 1900. It is under the auspices of Free Baptists and Disciples of Christ. It maintains a preparatory institute, a college, and a department of music. The admission requirements are about fourteen units. The Regents College entrance diploma is accepted. The college offers courses leading at the end of four years to the A B and B S. degrees. Of the enrollment of 107 students in 1910-1911, twenty-seven were in the college. The faculty consists of fifteen members.

**KIDDLE, HENRY** (1824-1891). — School superintendent and textbook author. He was principal of the first school established by the New York Public School Board (1841-1848). He was assistant superintendent of schools of New York City, under Samuel S. Randall (*qv*) from 1856 to 1870, and city superintendent of New York from 1870 to 1879. He was the author of textbooks in astronomy, physics, and grammar, of a series of school readers, and of several manuals for teachers, and was co-editor with Alexander Schem of a *Cyclopedia of Education*.  
W S M.

**KIEL, THE ROYAL CHRISTIAN-ALBRECHT UNIVERSITY OF**

— Founded by Duke Christian Albert of Holstein-Gottorp in 1665, the plans for its establishment dating back to the closing days of the Thirty Years' War, while the imperial decree had been secured as early as 1652 from Emperor Ferdinand III by Christian's father. The institution was opened under the most promising auspices, four faculties with a teaching staff of sixteen professors attracting no less than a hundred and forty students at the very beginning, a number which rose to almost nine hundred during the first decade of the university's life. After the death of the founder, the university was seriously impoverished as a result of the struggles which continued uninterruptedly between the house of Gottorp and the kingdom of Denmark. The history of the university at this time reads like that of an eighteenth-century American college, for we learn of an instructor who lectured on history, poetry, elocution, natural philosophy, politics, mathematics, and physics. But the attendance during the winter semester of 1762-1763 had shrunk to three students. Brighter days were in store for the university, however, for at this time the duchies of Schleswig and Holstein were reunited under Danish rule, and quiet was restored. In 1768

King Christian VII issued a mandate in accordance with which all residents of Schleswig-Holstein, who pursued university studies and looked forward to a career in their native land, were compelled to spend four semesters at the University of Kiel. Even under Danish rule the university continued to reflect German intellectual traditions and ideals, and politically, too, there was a strong sentiment among the faculty in favor of a reunion of the duchies with Germany. This pro-German attitude came to a head in 1848, when several of the professors sided with the duchy in its attempt to throw off the Danish yoke. As a result eight members of the faculty were dismissed after the disturbance had been quelled. After 1866 the university flourished under Prussian rule, in 1876 a new lecture hall was built, which was enlarged in 1902, while a library and a group of institutes and laboratories have been erected on the University hill. With these improvements in equipment, and with the growing importance of the city as a naval base, the attendance of the university has grown steadily of late and is still increasing, the summer enrollment being larger than the winter registration on account of the charming location of the city. The faculty of philosophy includes departments of agriculture and veterinary medicine, while the faculty of medicine makes provision for the study of dentistry and maintains, among others, a hygienic institute and a clinic for nervous and mental diseases. A student union, the Seeburg, situated on the shore of the bay, and, with the exception of the Palæstra Albertina at Königsberg, the only one of its kind in Germany, has recently been completed. The library contains almost 300,000 volumes and over 25,000 manuscripts. The annual budget of the university amounts to approximately \$450,000. Among prominent former teachers of the university may be mentioned Von Jhering in law, Stromeyer and Cohnheim in medicine, Pfeiderer in philosophy, Dahlmann, Droysen, Waitz, and Von Treitschke in history, Curtius, Mullenhoff, and Möbius in philology, Hertz in physics, and Eichler in botany. Klaus Groth, the famous Low-German (*Plattdeutsch*) author, was a docent at Kiel for several years.

The faculty is composed of 75 professors and 64 docents. In the winter semester of 1893-1894 Kiel ranked nineteenth in attendance among German universities, but by 1911-1912 it had advanced to the sixteenth position. In the latter year there were enrolled 1861 students, of whom 75 were auditors, the matriculated students being distributed as follows: Philosophy 708, medicine 506, law 320, theology (Protestant) 52.

**KINÆSTHETIC SENSATIONS** — The sensations which arise from moving the members or from lifting weights and similar experiences are known as kinæsthetic. It has been shown that there are sense organs in the muscles and tendons and in the tissues about the joints, and it has also been shown that the sensations of movement and the others of this group disappear or are weakened whenever these sense organs are anæsthetized, or when the posterior roots of the cord through which their impulses are transferred to the brain are destroyed, as is the case in the disease known as tabes. It is demonstrated that the kinæsthetic sensations arise from the sense organs in muscle, tendons, and about the joints

**KINASTON or KYNASTON, SIR FRANCIS** (1587–1642) — English scholar and poet, of a Shropshire family. He was at the University of Oxford 1601–1604, and also went to Trinity College, Cambridge, and took his M.A. there in 1609. He was called to the bar at Lincoln's Inn in 1611. In 1635 Kinaston published a Latin verse translation of two books of Chaucer's *Trilus and Cressida*. The object was to familiarize foreign as well as English readers with Chaucer's subject matter and is an excellent indication of the position of Latin at the period for such a purpose. Educationally, Kinaston is still more important on account of his project in 1635 to convert his own house in Bedford Street, Covent Garden, London, following Sir Thomas Gresham's (*q.v.*) example, into a college, which he agreed to furnish with books, manuscripts, musical and mathematical instruments, paintings, statues, etc., as well as charts, experiments, secrets, and demonstrations. He drew up *The Constitutions* of the college, which he termed the *Musæum Minervæ* (printed 1636). The normal course was to be for three years and a half, though it could be prolonged to seven years. It was to be confined to gentlemen. The object of the institution was to prepare the nobility and gentry with all necessary instruction (*e.g.* in languages) before undertaking foreign travel, which was then a part of educational equipment. The officers were: I. The Regent (in the first instance Kinaston himself), who was to "see performed" — Heraldry, Blazon of Coats and Arms, practical knowledge of Deeds and Evidences, Principles and Processes of Common Law, Knowledge of

Antiquities, Coins, Medals, Husbandry, etc. II. The Doctor of Philosophy and Physic III. The Professor of Astronomy who was to teach Astronomy, Optics, Navigation, and Cosmography. IV. The Professor of Geometry to teach Arithmetic, Analytical Algebra, Geometry, Fortification, and Architecture V. The Professor of Music to teach skill in singing and music, to play upon Organ, Lute, Viol, etc. VI. The Professor of Languages for Hebrew, Greek, Latin, Italian, French, Spanish, High Dutch VII. The Professor of Defence, to impart skill at all weapons and wrestling.

Other subjects to be taught in the *Musæum* were Riding, Dancing and Behavior, Painting, Sculpture, Writing. Further, Kinaston intended to have attached a school for "the young gentlemen whose parents are desirous to have them brought up in the *Musæum* from their first years." As much as possible all the subjects were to be treated "*by demonstration and experiment*." Every year each professor was to give some rarity to the library from his own branch of learning.

It was provided in one of the regulations that opportunities should be taken by pointing to examples of the leaders in their own time and of their own ancestors to train the scholars of the institution to serve as "an example, help, reason, and happiness" to their inferiors. This project fell through on the death of Kinaston in 1642. F. W.

WATSON, FOSTER. *Beginnings of the Teaching of Modern Subjects in England* (London, 1905)

**KINDERGARTEN, THE** — An institution for furthering the systematic development of children below the school age by the organization of their natural play instincts in accordance with the principles upon which development is based. The name, which signifies a children's garden or garden of children, was selected by its founder, Friedrich Froebel (*q.v.*), because it expressed the idea which he wished to convey, of development directed by a knowledge of the organism to be developed, and aided by the selection of a right environment. There is another aspect of the kindergarten, however, — its social aspect, — of which this name gives no suggestion. From this standpoint it has been defined as "a society of children engaged in play and in various forms of self-expression, through which the child comes to learn something of the values and methods of social life without as yet being burdened by its technique." These widely differing definitions indicate the complexity of the institution.

The kindergarten was the product of Froebel's mature years, since he had been a teacher

for nearly a quarter century before the idea of such an institution came to him. It is with the kindergarten that his name is chiefly associated, however, and upon it that his fame will ultimately rest. He himself considered the evolution of the kindergarten as the crowning achievement of his educational career, the supreme effort of his creative genius. This was due in part to the fact that he considered it the true foundation for effective school work and therefore the right beginning of all education, and in part to the fact that it embodies as in a nutshell the aims, means, and methods of education as he conceived it.

**Evolution of the Kindergarten** — The doctrines which the kindergarten embodies were derived from many sources. While Froebel was still a student at the University of Jena, he came into contact with the idealistic philosophy of which that university was the center, and by later study he made it his own. That philosophy interpreted the universe as an organic whole developing by means of a self-developing spiritual principle, and man as a part of that whole, whose end is to realize himself as one of its members by means of his own self-activity (*q n*). It interpreted the institution of society as expressions of man's spiritual nature, and held that that spiritual development of the individual could only be effected by participation in them. These views led Froebel to form certain important educational conclusions, — that education is in reality a process of development, that because man is spiritual and therefore creative, his development must be effected by means of creative self-activity, that since his spiritual development is achieved by participation in the organized life of his fellows education must be social, and that the best agency for his development during the early years is the child's own characteristic form of activity, play. All these doctrines Froebel had accepted and applied in his work with children of the customary school age for many years. The idea of an institution for young children in which play organized in accordance with these principles should be the sole educational agency did not occur to him until he was forced to consider the needs of a group of young children in an orphanage in Burgdorf, Switzerland, to the directorship of which he had been appointed in 1835. It was toward such an institution that his thought had been logically tending for some years, and it is not surprising that when the idea dawned upon him, he should have given several years to its elaboration.

In the institution which Froebel conceived he wished children to play with the freedom which they feel in the home, and the person in charge to organize and interpret their play experiences in the spirit of the mother but with an insight that the mother does not ordinarily possess. The carrying out of his idea, therefore, meant that the child gardener must be

able to meet the children upon their own plane and lead them to a higher one by guiding their natural play impulses. Froebel saw, however, that, if play was to become an educational agency in this sense, it must be organized in several respects. The customary forms of play needed to be analyzed and classified with reference to the ends which each tends to accomplish in the child's development, and a progressive series of play instrumentalities needed to be devised by which that development could be effected. More important than even these was the determining from a careful study of children what the leading play interests are during the years for which such a form of education was intended, and how each may best be organized. In providing for the child's physical development by means of play, for example, his physical status during the years between four and six, and the nature and degree of development possible to him, must be determined before plays and games for the furthering of that development could be devised. A like study was needed before the plays and games that tend toward social cooperation or toward constructive or æsthetic effort could be created.

Although the knowledge required for such a study of children's play needs was inadequate at this period, Froebel undertook the organization of the play instrumentalities which his institution called for. These instrumentalities fall naturally into two groups, those in which no material is needed, and those in which the idea requires a medium for its expression. In the first belong the games of social cooperation and control. These are mainly of two kinds, — the dramatic games whose purpose is to represent the activities of groups of social workers, such as the farmer, the carpenter, and others, and the games of skill by means of which the qualities needed for successful social effort are cultivated. The instrumentalities which Froebel invented for the progressive development of the children's constructive and æsthetic power are the materials known as the "gifts and occupations." He had employed modeling, weaving, sewing, etc., with older children, and it was with the adaptation of these to young children that he now began. He saw, however, that although progressive exercises in each provided for continuity in separate lines, the relation between them, which he considered necessary, was lacking. He recognized the need, therefore, of a principle of connection, not alone to bind together the various forms of creative expression, but to furnish a basis for expression of any kind. This gave him the idea of an organized series of playthings from which children should gain a progressive series of sense impressions. This was the root idea of the kindergarten gifts.

For the first of these he selected a set of balls of the six standard colors, for the second, the three fundamental forms, and for the several

immediately following, cubes differently divided. From these he wished the children to gain, progressively, ideas of color, form, number, dimension, etc., and the ideas thus gained he intended them to work out creatively by means of plastic material. The gifts as an organized series, therefore, furnished the central principle which bound the several forms of play material into an organic whole. The organization of a system of instrumentalities which embodied the idea of progressive development that he wished to see effected in the child was therefore an important step in the evolution of the kindergarten itself. By the establishing of unity in the material for play, Froebel felt that he had made it possible to bring about the higher unity required in true educational effort, — that between the child and the means by which his development is to be effected. There are additional reasons, however, for Froebel's choice of the objects designated as gifts. According to the thought of the period, children have foregleams of great principles in the form of "anticipations" and "premonitions." These principles, it was believed, could be brought to their consciousness by play with the objects that symbolize them. The gifts are, therefore, not alone the means of conveying fundamental sense impressions, nor yet agencies for the exercise of creative self-activity; they are symbols of universal truths for children to absorb. By play with the first gift, Froebel believed that they would become conscious of the principle of unity, and by play with the second of the principle of mediation of opposites. So important did he consider this second principle that he not only embodied it in a gift, but made it the principle of method in the gifts and occupations alike. This feature of the gifts occasioned no little criticism when the kindergarten doctrines were brought to the test of modern thought, as will be seen later.

**The Kindergarten in Practice** — With the organization of the materials for play completed, the institution which Froebel had conceived could come into existence. As has been stated, the conception of such an institution came to him in Burgdorf, Switzerland, in 1835. As an objective fact, it came into existence in Blankenburg, Germany, in 1837. It is because the name "kindergarten" was not adopted until 1840 that the latter year is given as the date when the first kindergarten was established. Blankenburg was a city of 2000 inhabitants, about two miles from Keilhau, the scene of Froebel's earlier labors. It afforded many opportunities for the gardening and nature excursions upon which Froebel laid great stress. A building adapted to the needs of the experiment was difficult to find, however, and the little company of children met in a disused powdermill. In spite of the unattractive surroundings, the new institution was at once successful. Froebel entered into a

play with the children so completely, and the materials which he presented were so attractive, that the children were carried away with enthusiasm, and never realized that their play was being directed. The exercises were simple and informal, but similar in general character to those of the kindergartens at present. The children formed a circle upon entering and sang songs of greeting and thanksgiving. Then came a period of play with the organized materials in which the children's experiences were taken as a point of departure, and given meaning and relation by Froebel. After this the children marched to the gardens, the woods or fields, or the playground out of doors. In both the games and the nature observations, the children's immediate interests formed the starting point, and from these they were led naturally to games or observations controlled by those in charge. After the games or out-of-door period, came another period of play with the organized materials, and sometimes stories were told. From all accounts, Froebel indeed "lived with the children." One writer says of these first kindergartens: "Although the kindergarten system was then still in the making, its spirit was there in a freshness and wholeness that can hardly have been surpassed since."

The kindergarten has made great progress since Froebel's day, although the play program which he devised has not been materially altered. The doctrines which the kindergarten embodies are more clearly comprehended at the present; the agencies which it employs have been greatly improved; the program of exercises has been elaborated; and the kindergartners are better prepared to realize its ideals. A more fundamental knowledge of the child's nervous and muscular development has shown the need of a larger material and more active games than those which Froebel planned. A clearer insight into his modes of thought has created stories suited to his comprehension yet tending toward the formation of true literary tastes, and a better acquaintance with the facts of his musical development has brought into existence songs that are childlike in thought and musical feeling, but in harmony with the fundamental principles of musical art. The kindergarten song, picture, and story are recognized to-day as the best that the arts which they represent can furnish.

The program of exercises in the kindergarten has changed somewhat since Froebel's day, although not wholly for the better. There are but few kindergartens at present in which the out-of-door work receives the attention which Froebel gave it or which its importance merits. Many other phases of the kindergarten program have been elaborated. The opening period, originally devoted mainly to songs, now generally includes more or less organized conversation upon some phase of the children's experience. A period is frequently

devoted to musical interpretation, voice work, or picture interpretation, but the games, and gifts, and occupation exercises still receive the greater share of attention. In many kindergartens the gift and occupation exercises overshadow everything else.

The work of the kindergarten has been much criticized of late as being too formal to be in accord with the principles of child development. The foundation idea of the kindergarten is that of development, and formal work is therefore out of harmony with its fundamental conception. There is but one phase of kindergarten procedure which has a tendency toward routine, — the work with the gifts and occupations. Froebel devised these as one of several means to the child's development, apparently of no greater significance than the games or the garden and nature work. As time passed, the balance between these several agencies became disturbed, some being neglected and others overemphasized. The out-of-door work has been almost eliminated, as has been stated. The work with the gifts and occupations, on the contrary, has received an inordinate emphasis, for reasons given later. But to select for emphasis the one among the several agencies that tends toward the formal and the mechanical is to give the work a direction that its founder could not have intended, since it is out of harmony with the fundamental idea which the kindergarten embodies. It is the undue emphasis that has been placed upon the kindergarten material that has caused the work of the kindergarten to become stereotyped and formal. It is against this feature of its work that the "liberal" movement, discussed elsewhere, is directed.

**Status of the Kindergarten in Different Countries.** — The progress which the kindergarten has made during the seventy or more years of its existence has surprised even its friends. It has found its way to every continent and its literature has been translated into the world's leading languages. It was introduced into almost every country in Europe during the twenty years following Froebel's death in 1852, by his most distinguished pupil, the Baroness von Bulow. In some of these countries the movement has made little or no progress, and efforts in its behalf are unorganized at the present time; in others the kindergarten is replacing the infant school (*q. v.*), which had been organized to meet the needs of the pre-school period before the kindergarten came into existence, and in others it has become an organic part of the school system. In the countries of northern Europe the existing kindergartens are mainly private or charitable. They have existed in Holland since 1857 as a result of the Baroness von Bulow's influence, and may now be found in all the large cities. Institutions for kindergarten training have been established in Leyden and Rotterdam. The state, however, does not

concern itself with these. Denmark sent students to Dresden in the early seventies to be trained by the Baroness von Bulow, that they might introduce the kindergarten into their own country. As a result, the movement has had a steady growth, and kindergartens may be found in the larger cities. Copenhagen has as many as fifty, and a well-equipped training school. There are no kindergartens in Norway and very few in Sweden. In Finland, however, there are thirty or more, and a training school at Helsingfors. Russia sent students to Germany for training as early as 1861. There is a training school at St. Petersburg and some kindergartens in the large cities.

In Spain and Portugal, too, as well as in some of the countries of southeastern Europe, the kindergarten has but a slight foothold. A kindergarten was opened in Oporto in 1879, and at about the same time Spain sent several students to Dresden for training. Upon their return they established some kindergartens and a training college at Madrid. The king of Spain was trained by one of these kindergartners. In the early seventies several wealthy Greek women went to Dresden for training and upon their return established kindergartens in Greece. Kindergartens have also been opened in Bulgaria, Roumania, and Servia, but in all of these countries active effort in behalf of the kindergarten is slight. In many European countries the kindergarten has had a greater growth and has exerted a marked influence. In Germany, however, but little recognition has been given to it in spite of the effort of the Baroness von Bulow and other devoted friends of the cause. The centers of kindergarten influence in Germany have been Hamburg, in which Froebel's widow settled in 1854 to take up the work of kindergarten training, Dresden, which the Baroness von Bulow made the chief scene of her labors, and Berlin, in which city Froebel's niece and co-worker, Madame Schrader, built up the well-known Pestalozzi-Froebel Haus. As a result of these and other efforts the kindergarten is gaining strength in Germany, although it is not likely that it will be made a part of the system of public education. At the present time, kindergartens are to be found in all the large cities, supported in whole or in part by municipal grants. The *Bewahranstalten*, or caretaking institutions for children below the school age had gained favor in Germany before the kindergarten was conceived, and such institutions share with the kindergarten in public favor. In 1902 it was estimated that there were over 800 kindergartens and *Bewahranstalten*, in which 79,000 children were enrolled.

In Switzerland kindergartens have not been made a part of the school system, but their work is recognized as the true basis for that of the school, and the private institutions are rapidly being transferred to municipal authority. As early as 1876, 206 private *crèches*

were converted into kindergartens under state control in Geneva, under the able leadership of Madame de Portugall. In 1906 there were forty-seven municipal kindergartens in Zurich, and seventy-three in Basel. There are also several well-equipped training colleges.

In Italy kindergartens are private and communal, although they receive grants from the general government. Kindergartens have been established in at least one fourth of the communes, Milan alone in 1908 having sixty-five under communal, and eleven under private, control. Since children are allowed to enter at the age of two and a half years, many of the so-called kindergartens are in reality *crèches*, or day nurseries, in which the educational features of the kindergarten are wanting. The lack of trained kindergartners is the weakness of the Italian kindergartens. There are some good training courses in connection with the normal schools, and excellent private training schools in Naples, Verona, and Rome. In the last named city is the Royal Froebel Institute, which received an endowment from Victor Emmanuel II. (See MONTESSORI METHOD.)

England and France are the principal European countries that have retained the infant school instead of adopting the kindergarten. But the Froebelian doctrines have had a marked influence upon the infant schools of England, and the movement in that country is of great interest. The first kindergartens were opened in London and Manchester in 1854, as a result of the Baroness von Bulow's effort. Many of the leaders are known to kindergartners the world over. They have directed their efforts, not to the establishing of kindergartners, but to the modification of the methods employed in the infant schools (*q. v.*). Official recognition of Froebelian principles was given in the Education Department's Circular (322) on the *Instruction of Infants* (1893). This necessitated the organization of courses of instruction for the teachers, the establishment of courses in the training colleges, and the inspection of the work done. In 1896 there were thirty or more institutions that gave kindergarten instruction, and ten kindergarten colleges proper. This has proved a task of some magnitude in view of the fact that in 1900 there were enrolled in the infant schools of England 622,494 children below the age of five years. Of the results, Mr. R. E. Hughes says in his *Making of Citizens*, "In the best English infant schools a profound revolution has taken place during recent years. Formal lessons in the Three R's have disappeared and the whole of the training of the little ones has been based on the principles of the kindergarten as enunciated by Froebel. Much of the old routine still remains, nevertheless there is no part of the English educational system so brimful of real promise as the work that is being done in the best Infant Schools."

(See ENGLAND, EDUCATION IN, INFANT SCHOOLS.)

The Baroness von Bulow's efforts in France in 1855 resulted in many reforms in the infant schools of that country. Their reorganization upon a Froebelian basis continued for several years, but as the result of the feeling aroused by the Franco-Prussian war, everything German, even the name kindergarten, was rejected, and progress in that line came to an end. In 1906-1907 the *Écoles Maternelles* enrolled 651,955 children between the ages of two and six years. Their work is well organized and their equipment fair, but their educational work leaves much to be desired. (See FRANCE, EDUCATION IN.)

If the real purpose of the kindergarten is to furnish the right beginning for the work of the school, that purpose is best realized in Belgium and Austria-Hungary, since these countries have adopted the kindergarten as a part of the school system. Belgium had a system of infant schools for children between the ages of three and six years, but in 1857 the Baroness von Bulow convinced the Belgian authorities of the wisdom of reorganizing these on a kindergarten basis, and the *Écoles Gardiennes* or *Jardins d'Enfants* are now in effect true kindergartens. In 1905 there were 2771 such institutions in the country, which were attended by 258,149 children, one half of those between the ages of three and six in the country. In completeness of equipment, in the preparation of its teachers, and in the quality of work done the *Jardins d'Enfants* of Belgium may well serve as a model for other countries.

In Austria-Hungary infant schools had been organized before the kindergarten was invented, but the influence of Froebel began to be felt even during his lifetime, and the transformation of the infant schools was gradually effected. In 1872 kindergartens were made a part of the school system. In 1903 there were 77,000 children between the ages of three and six years in the kindergartens of Austria, and 154,000 in those of Hungary. There is also a completely organized system of day nurseries, which enrolled 152,000 children. The kindergartens of Hungary are among the best in the world and may be classed with the best Swiss and American kindergartens. The equipment is admirable and the spirit and training of the teachers excellent. There are many good training schools.

The kindergarten has gained a foothold on other continents also. Those in Asia and Africa are in the main the result of missionary effort by the leading churches of the United States. In Buenguella, Portuguese West Africa, there are kindergartens in four out of five mission stations. There is another such kindergarten in Umtali, Rhodesia. There are a few kindergartens in other parts of Africa,—in Cisambia, Bailundu, Machakos, and Cape Town.

## KINDERGARTEN

In Asia the kindergarten is in large measure the product of American missionary enterprise. In Asiatic Turkey there were in 1896 twenty-eight kindergartens, the outgrowth of a mission kindergarten opened in Smyrna in 1885. In India there are several kindergartens and training schools of missionary origin,—one at Lucknow, in connection with Thoburn College, and one at Sholapur. Kindergartens may also be found in Calcutta, Bombay, Cawnpore, Madras, and several other cities. There are several kindergartens in connection with missions in Burma, and at least two in China, one in Foochow, and one in Penang. In Foochow there is also a training school. In Japan the kindergarten is a conspicuous part of the missionary work. A kindergarten and training school were organized in Kobe College, one of the important centers for training of girls, in 1889, under the leadership of Miss Annie L. Howe. This has had a wonderful development. Several other training schools have been organized since that time.

In Japan, however, the kindergarten had been adopted before it became an agency in the missionary work of that country. When Japan reorganized its educational system upon a western basis in the early seventies, it sent to Germany for some one to introduce the kindergarten into its educational plan. As a consequence, a kindergarten was opened in connection with the Female Higher Normal School in Tokyo, in 1876, and the adoption of the kindergarten as a part of the public school system was provided for. In 1904 there were 185 public, and nearly a hundred private, schools. In these 24,000 children between the ages of three and six years were enrolled. In buildings, gardens, playgrounds, and in general equipment the kindergartens compare favorably with the best in America. Training work has not been adequately organized, however, and many kindergartners are not well trained. This is not surprising in view of the many difficulties to be overcome. The fact that Japan has already done so much is proof that she will do still more. The fact that the leading country of the Orient has adopted the kindergarten will insure a like adoption by other Oriental countries in the near future. (See JAPAN, EDUCATION IN.)

In Australia the kindergarten has not gained as strong a foothold as one would expect. The school system is based upon that of England and the problem is therefore that of substituting the kindergarten for the infant school, or reorganizing the latter in accordance with the principles of Froebel. The centers of kindergarten work and influence are Sydney, Melbourne, and Adelaide. Sydney stands at the head of the movement in Australia. It has a fully equipped training college, with a staff of American trained teachers. The college has about fifty students. In this city the tendency is to substitute kindergartens

## KINDERGARTEN

for the infant schools, and there are therefore several public kindergartens, as well as private ones. The Educational Department of New South Wales has become convinced of the value of kindergartens, and is establishing them in the public schools of the province wherever possible. The work in Melbourne has also been of great value. Something along kindergarten lines was attempted in the infant schools of this city as early as 1887. In 1900 the reorganization work of the infant schools upon a kindergarten basis was begun and much has been accomplished in that direction. Reforms in this direction have also been introduced in Adelaide.

In South America the kindergarten has apparently made but little progress. Some kindergartens were organized in Buenos Aires and elsewhere in Argentina in the nineties, but the training of the kindergartners was apparently very inadequate, and in 1900 all these in Buenos Aires were closed by the Board of Public Education. Miss Sara C. Eccleston, who has given kindergarten instruction in the normal school at Buenos Aires for nearly twenty years, said with reference to this that "the imitations which were permitted to flourish for a time have been a great hindrance to the advance of the system." She adds, "As there are now several members on the board who have an idea of how a genuine kindergarten should be conducted, it is to be hoped that what seems to be a blow at the system is but a means to reestablish the institutions under proper conditions." What the present status of the kindergarten in that country is could not be ascertained. In Uruguay the introduction of kindergartens was arranged for by the sending of students to Germany and Belgium for training by the government. The results of this effort made in 1890 could not be learned. In Chile some kindergartens have been opened, and some kindergarten instruction is given in the normal school at Santiago. In 1908 the government sent its leading kindergartner to the United States for observation. This will doubtless give the movement in that country an impetus toward kindergarten effort. In Brazil one or two kindergartens have been established as a result of missionary effort in the United States. In Mexico the kindergarten situation is not unlike that in the countries of South America. There are ten or more kindergartens in the City of Mexico, and a few in other parts of the country. Here, too, the training of kindergartners is very inadequate, since it is only such as can be obtained by the study of kindergarten books. The attempt is being made to improve this by improving and developing the kindergarten instruction in the Girls' Normal School of the City of Mexico.

In the United States the kindergarten has found a cordial reception and its doctrines have exerted a great influence. This country

has a creditable number of kindergartens, but the success of the movement is not measured by that alone; it is measured as fully by its reorganization of the school, and the application of its principles to other fields. The first kindergarten in the United States was opened in Watertown, Wis., in 1855, by Mrs. Carl Schurz, a pupil of Froebel. During the next fifteen years ten or more German kindergartens were organized in German-speaking communities. The first kindergarten for English-speaking children was opened in Boston in 1860, by Elizabeth P. Peabody, who is usually considered the apostle of the kindergarten in the United States. In 1868 Madame Matilde Kriege and her daughter came from Germany to organize kindergarten training in Boston, and in 1872 Miss Marie Boelte, now Madame Kraus-Boelte, organized kindergarten training classes in New York City. The following year, her pupil, Miss Susan E. Blow, in cooperation with W. T. Harris (*qv*), opened the first public school kindergarten in St. Louis, Mo. The movement grew rapidly and St. Louis became one of the chief centers of kindergarten influence. At about the same time a kindergarten was opened in the German-English Academy of Milwaukee, Wis., and training courses were organized both in German and English by the president, W. N. Hailman, and his wife, Eudora L. Hailman. The first kindergarten in Chicago was opened in 1874 by Mrs. Alice H. Putman, and training work under her direction was inaugurated soon after. In 1880 four hundred kindergartens had been opened in thirty different states, and kindergarten training had been organized in ten of the leading cities. During the decade from 1880 to 1890 kindergarten associations were organized in all the important cities of the country for the promotion of the kindergarten cause. Many of these opened kindergartens in the poorer parts of their respective cities, and thus proved the value of the kindergarten to educational authorities. In consequence, kindergartens were increasingly incorporated into the school system. From 1890 on, the increase in public school kindergartens has been rapid. In 1903-1904 the *Report of the Commissioner of Education* showed that there were over 3000 public kindergartens, which were attended by nearly 200,000 children. The number of private kindergartens is supposed to be about 1500.

With the growth of the movement there has been a great increase in the number of kindergarten training schools. At first these were all private or were supported by kindergarten associations. There are at least a hundred of these at present. In addition, kindergarten training departments have been organized in more than seventy state normal schools, and nearly twenty colleges and universities. This growth has been made possible by the enactment of laws in twenty-seven states,

legalizing the expenditure of public school funds for the education of children below the legal school age. In eight states the kindergarten may be established without legislation. The kindergarten therefore has a legal foothold in all but eleven states. It has also been adopted in Cuba, in Porto Rico, and the Philippines.

The kindergarten in the United States has been the stimulus to the adoption of the kindergarten in Canada. This was the direct result of a visit made to the kindergartens of St. Louis by Mr. J. L. Hughes of Toronto in 1882, at the request of the department of education of the Province of Ontario. The result was the adoption of the kindergarten as a part of the school system in that province, Miss Ada Marean, now Mrs. Ada Marean Hughes, being appointed supervisor of kindergartens in Toronto. Before the end of the decade the other cities of the province had adopted kindergartens, and training departments had been organized in the normal schools at Toronto, Ottawa, and London. In 1905 there were 130 kindergartens in the province, which were attended by 12,000 children.

In the province of Quebec there are public kindergartens in Montreal only. The movement in this city was inaugurated in 1892, and in 1905 there were sixteen public kindergartens in the city and suburbs. There is a kindergarten training department in the McGill normal school. In other Canadian provinces the kindergarten has found less foothold. In New Brunswick there have been private and mission kindergartens since 1880, but it was not until 1910 that public kindergartens, two in number, were opened in St. John. In Nova Scotia there are three public kindergartens, and a kindergarten training department in the normal school at Truro. In Winnipeg there are only private and charitable kindergartens. The need of kindergartens in the western provinces is conceded, however, and its extension to that field is but a matter of time.

**Influence of the Kindergarten.** — The recognition which the kindergarten has received the world over is proof that it possesses exceptional educational value. Its doctrines, based upon the conception of evolution before the theory had been worked out, are in fundamental accord with modern thought, and have in recent years received signal indorsement from the evolutionary sciences. As the world's thought has been reconstructed on the basis of these sciences, the value of the kindergarten has been increasingly recognized. The critical study which it has received during recent years has satisfied educational experts that the conception of education which it embodies is essentially the true one. In spreading that conception, and in indicating the reconstruction in general education which must follow its acceptance, the kindergarten has been a

significant influence. By showing the vital interest that children take in doing, the kindergarten demonstrated at one stroke that activity, based upon the child's stage of development, forms the true basis for education. By revealing the child's delight in beauty, it indicated the value of art as an educational factor; and by illustrating the pleasure and profit that children derive from games and other forms of social cooperation it suggested a means for the child's social development that had not thus far been utilized for educational purposes. It demonstrated these truths for one period only, but from that demonstration their application to the rest could easily be inferred. The application of these truths to educational procedure beyond the kindergarten has as yet made little progress except in a few countries. Although kindergartens flourish in Germany its doctrines are wholly unrecognized in the work beyond the kindergarten. But in Belgium, Switzerland, Austria-Hungary, and Italy, these same doctrines have exerted a marked influence, not alone in transforming the infant schools, but in reconstructing that in the grades beyond. And although England has not adopted the kindergarten, a complete reorganization of the infant schools is in progress on the basis of its principles, and a reorganization of the work beyond as well. It is in the United States that the application of the kindergarten doctrines to the work beyond the kindergarten has made the greatest progress, and what follows applies mainly to that country. The fact that the elementary curriculum is being reconstructed in the United States on the basis of the child's developing powers at different periods, that subjects involving activity, such as art and manual training, are being accorded an important place there, and that games and other forms of cooperative effort are being incorporated into school life, -- all these changes are due in no small degree to the influence and example of the kindergarten.

It is not alone in the reorganization of the curriculum upon a psychological basis, however, that the influence of the kindergarten is apparent; it is discernible also in a new conception of method. Upon the old basis little was asked of the child in the educational process except receptivity. According to the new, as illustrated in the kindergarten, the child must make his contribution of self-active effort before the teacher can furnish the interpretation and guidance which constitute her contribution. On this basis, educational method is a process of interaction between the child and the teacher, in which the child contributes the impulses and interests, and the teacher the organization of these toward their educational ends. The attitude toward children which this calls for is illustrated by the kindergartner, whom the children regard as a companion rather than as a teacher. Such a

method calls for even more than sympathetic insight, it calls for a knowledge of the children's progressive development at different stages, and the means of furthering it that was not demanded of the teacher in the earlier day. That the spirit which this conception of method implies has already permeated the school in large measure is apparent. The work in art, in manual training, in music, and in language shows that the teacher seeks to secure from the children original expression, upon which she may exercise her function of guidance, for the purpose of leading them to higher levels of insight and power.

The influence of the kindergarten is apparent in still another direction. The school is organized upon a monarchical principle. Its chief virtue is obedience to an external authority. The practice of that virtue does not, however, fit children for a self-governed life among their equals. The qualities needed for such a life are acquired unconsciously in the kindergarten by participation in cooperative play. That institution is based upon the principles of democracy. It has, in fact, been called "the republic of childhood." It seeks to form correct habits of social action in children, but to do even more, -- to lead them upon the basis of their own social experiences to a comprehension of and a recognition for the need of social laws. As a result of an insight into this truth the school has recognized that the development of self-governing power in children may be made an organic part of its procedure, and that such development is quite as important an educational end as the teaching of the school arts. It is, therefore, progressively organizing its work upon a cooperative and self-governing basis, and is becoming, like the kindergarten, a miniature society in which the laws underlying social coordination and control are learned by practice.

These are a few of the more important lines in which the kindergarten has influenced general education. It is difficult to trace that influence, however, since the doctrines of Froebel have become interwoven with allied doctrines derived from other sources. Dr. Monroe says: "The Froebelian movement is characterized by an emphasis upon the importance of the child, upon his interests, experiences, and activities as the starting point and means of introduction, and by an improvement in the spirit, purpose, atmosphere, and morale of the schoolroom. Whenever the emphasis in school work is placed upon the activities of the child rather than upon the technique of the process of instruction, and whenever development of character and personality is sought rather than mere impartation of information and training of intellectual abilities, there the Froebelian influence may be recognized."

**Modern Tendencies.**—The effort to apply the doctrines of the kindergarten to general education had an effect upon the kindergarten

itself that was hardly anticipated. Upon its adoption by the school the kindergarten was brought to the test of present-day knowledge of the child's development, — a knowledge far greater than that possessed by Froebel himself.

That test revealed the fundamental truth which the kindergarten embodies, but it revealed also defects hitherto unrecognized — the result either of Froebel's inadequate knowledge of the facts of child development or of his interpretation of these facts in a manner not sanctioned by modern scholarship. The smallness of the kindergarten material and the lack of adequate activity in the games resulted from Froebel's inadequate knowledge, the symbolic basis in the gifts grew out of his belief that the children have anticipations of universal truths in advance of experience, and that they may become conscious of these by means of play with materials which symbolize them. This challenging of kindergarten theory and practice caused considerable hostile feeling among kindergartners who had thus far accepted the Froebelian doctrines without question, and considered the doctrine of symbolism as not only sound because sanctioned by rational psychology, but of especial importance. It was in fact regarded by many kindergartners as the keystone in the arch of kindergarten education and the justification for the exaltation of kindergarten instrumentalities. In time the differences between the theory and practice of those holding these different attitudes became more clearly defined and the terms "conservative" and "liberal" were adopted to designate them. The work of the two schools which have thus grown up shows considerable divergence. That of the conservative school follows quite closely the traditional lines, although it shows that the criticisms have not been without effect. In consequence the size and quality of the materials has improved in even the most conservative kindergartens; the games are better adapted to the children's physical needs, and the "occupations" are used with a better appreciation of the principles that underlie art education.

The theory and practice of the liberals has not been fully worked out as yet. They recognize the need for an interpretation of the universe such as philosophy gives as a basis for education, but they maintain that in the nature of the case no such interpretation can be final. Any interpretation implies an adequate basis of facts, and thus the inductive science alone can furnish. Although the end of education must be found in the interpretation of the facts, they agree with the educational expert in believing that the method of education cannot be deduced from philosophy but must be found in the observed facts of child life, i.e. in the sciences. Basing their method upon genetic psychology, the liberals interpret education according to Froebel, as the progressive organization of the impulses that have

educational significance, — the impulses to communicate, to dramatize, to represent, and to construct. They value the kindergarten instrumentalities chiefly because of their power to satisfy and thus to organize these various impulses, and consider that the Froebelian ideal of education has been realized when the children's responses to the stimuli of the materials have been guided to a higher plane than they could themselves reach. The liberals, therefore, use the kindergarten material "on a basis of selection and elimination rather than as a related whole whose value is lost if the charmed circle of unity be broken." Thus the whole tendency of the liberal movement is away from the formalism into which the work of the kindergarten has fallen and which has brought it into disfavor, and in the direction of that for which it was originally created, — the child's natural development. The movement has already had an appreciable effect in lessening the mechanical work against which criticism has been directed and in bringing back into the kindergarten the childlikeness that prevailed there in Froebel's own day. The liberal kindergartners believe that the reconstruction of kindergarten thought and practice, which they are attempting to effect, will not only make the kindergarten a more perfect instrument for its mission to the world's little children, but a more perfect one likewise for the dissemination of the doctrines which it embodies, — the doctrines of the new education. N. C. V.

**KINDERGARTEN AND THE ELEMENTARY SCHOOL.** — See KINDERGARTEN.

**KINDERGARTEN, HYGIENE OF THE**

— The physical characteristics of the child of three to six are such that the primary aim of the kindergarten should be healthful development and protection from disease. Not only is the child at this period growing rapidly and its brain undeveloped, but its organism is poorly protected from contagious disease. The constituents of the blood are different in case of the child and in case of the adult. The number of white blood corpuscles in the blood, whose function is to destroy invading germs, *i.e.* the leucocytes with bactericidal power, according to some investigators, is much less. In other ways the child's protection seems to be inferior. Experiments upon animals have shown that young animals are likely to be more susceptible to contagion than mature animals, and the statistics of the ordinary children's diseases show that most of them occur in the early years of childhood. The mortality, also, is usually greater in the early years. It has been estimated that more than 90 per cent of the mortality from the ordinary children's diseases, scarlet fever, diphtheria, measles, and whooping cough, occurs before the age of ten. (See **CONTAGIOUS DISEASES, MORTALITY AMONG SCHOOL CHILDREN**.)

Most of these diseases not only occur more frequently, but are more fatal in the early years. Infantile paralysis is perhaps the only marked exception. In case of this disease it is said that, while children are more frequently attacked, it is more fatal to adults. Extended studies of measles have given emphatic evidence of the importance of protecting children at the kindergarten age. Studies in Munich and Graz indicate that the mortality among children between two to five years of age is between 26 per cent and 5 per cent, while among children from five to ten years of age it is only from .1 to 4 per cent. In other words, if an epidemic of measles occurs in the kindergarten, out of a thousand cases forty children are likely to die, while, if it is possible to postpone the epidemic, even to the primary school age, there are likely to be only three or four fatal cases in a thousand. (See **CONTAGIOUS DISEASES**; and articles on separate diseases, *e.g.* **COLDS; DIPHTHERIA**, etc.)

Hence, the first duty of the kindergarten is to protect the children. It should never become the breeding-place for the school diseases. For this protection of the children the kindergartners must have an intelligent training in hygiene, and special records of the health condition of the kindergarten children should be kept. It should be possible for the teacher and the higher school officials to know at once from adequate records just how many unprotected children there are, or how much inflammable material is present in the class whenever a case of contagious disease occurs. Only in this way can rational and effective measures be adopted. If a case of measles,

for example, occurs, and most of the children have not had the disease, the kindergarten should at once be closed. If, on the other hand, the majority of the children have already had the disease, the individual children that are unprotected can be excluded, but closure is unnecessary.

In regard to the schoolhouse for the kindergarten, there is a growing opinion that as far as possible the work should be out of doors, and only in inclement weather should the occupations be in the house. Whether in or out of doors, the ordinary rules of school hygiene should be observed. Care should be paid to the children's eyes, children with defective hearing should have special attention; and cleanliness should be everywhere enforced.

The kindergarten room should be large and well ventilated, the walls plain with simple hospital base without wainscoting, or the like, to catch the dust. The chairs should be arranged for occupation so that the light comes from the left and the rear of the children and none of the children face the sunlight. The blackboards should be low, and in the toilet rooms the bowls and sinks low, individual drinking cups used, or better a fountain of the improved modern type provided. Individual towels, or paper napkins, or the like, should be used, the clay should be disinfected every day, and all kindergarten apparatus disinfected at intervals. Especially to be condemned are dry sweeping, the use of feather dusters, the common towel, and common drinking cup. (See **BLACKBOARDS, CLEANLINESS OF THE SCHOOLROOM, DESKS AND SEATS, DRINKING FOUNTAINS**, etc.)

The air of the kindergarten room should not only be kept clean and be of the proper temperature, probably not more than 65° F., but it should be moistened by suitable devices, if nothing better offers, by a large shallow vessel of water on the stove or radiator. The extreme dryness of the air in many schoolrooms causes discomfort and many colds and sore throats. (See **AIR OF THE SCHOOLROOM**.)

As the kindergarten occupations consist largely of physical exercise and the use of the voice, the best modern methods of cleaning should be used, a vacuum cleaner if possible; if not, sweeping with oil preparations or the kerosene oil brush at night and wiping off the furniture and apparatus with a moist cloth in the morning. (See **CLEANLINESS OF THE SCHOOLROOM**.)

Finally, especial care should be given in the kindergarten to the hygiene of the nervous system. At this period, when the brain is in process of rapid growth and development, when much of the nervous substance is immature, it is important that there should be no undue stimulation either by too complex and too fine occupations, by overstimulating plays, or by unduly exciting stories, and the like.

The interest of kindergarten children can be easily kept by simple occupations, exciting stories and occupations are unnecessary and unwise, and likely to leave the children in a *blasé* condition, unfortunate from the point of pedagogy, as well as that of hygiene. It is maintained by Professor Tyler, President Hall, and some others, that the fundamental nerve centers controlling the large muscles of the different physiological series, and functioning the simpler and larger movements must be developed in the early years, if the normal development and the health of the nerves in later life are to be insured. These fundamental nerve centers form the line of defense for the whole body, and any premature development of the accessory centers, those functioning in the finer and more complex movements, is distinctly to be condemned for hygienic reasons. Thus, the activity in the kindergarten should be spontaneous motor activity, as far as possible the simple plays and games and simple occupations. All of the gifts and apparatus should be large, the occupations and exercises should involve the larger muscles; all fine delicate and complex processes are out of place. For example, the use of a hammer in driving a nail is a more healthful occupation for the kindergarten child than the threading of a needle; for the former involves the use of the large muscles of the hand and the arm, while the latter requires the delicate and complex coordination of the muscles of the eye and fingers. Some kindergartners seem to suppose that if in the finer occupations the work is held at a suitable distance from the eyes, that is all that is necessary, but a great part of the children probably at the kindergarten have hyperopic eyes, and their aims are not long enough, so that it is possible for them to hold the book or the work at the proper distance. The larger occupations are also necessary for their positive value.

The main business of the child at the kindergarten age is physical growth and spontaneous motor activity. Thus the primary aim of the kindergarten should be to protect the child from disease at all cost, to give opportunity for spontaneous normal development, and to develop habits of healthful activity both physical and mental. All scholastic acquisitions are of secondary importance and any formal scholastic training is out of place, and, if obedience be taught, other necessary social training will come spontaneously from association in group activities.

In recent years, improvements have been made in the kindergarten and there is a growing interest in all matters of health pertaining to the kindergarten child. The reforms especially needed at the present time are the following: (1) Clear and emphatic enunciation of health and normal development as the primary aim of the kindergarten. (2) The training of all kindergarten teachers in school and per-

sonal hygiene (3) The adoption of modern methods of scientific cleanliness, which involve the abolition of common drinking cups, common towels, and the like. (4) The organization of the kindergarten out of doors for all occupations at all seasons of the year when the weather will permit (5) Care of the nervous system by the avoidance of all forms of premature stimulation, fine and difficult work, and the like (6) Competent health inspection with an adequate system of health records for each pupil and the adoption of modern methods in the management of contagious diseases

**KINDERMANN, FERDINAND** (1740-1801). — An Austrian educational reformer, born in Königswalde, near Schluckenau, in Bohemia. He studied theology at the University of Prague, where he received the doctor's degree in 1766. In 1771 he was called as pastor to the town of Kapltz in southern Bohemia and there devoted his energies to the improvement of the rural schools. He introduced manual and industrial training, and his work attracted the attention of the Empress Maria Theresa, who was keenly alive to the educational needs of her subjects. She appointed him as general inspector of the German schools of Bohemia, and raised him to the nobility with the title "von Schulstein." In 1790 he was made Bishop of Leitmeritz, where he continued to work for the education of the people until his death.

**KING, CHARLES** (1789–1867). — President of Columbia College, educated in England and France. He engaged in commercial and journalistic pursuits, but took an active interest in educational matters. From 1825 he was one of the trustees of Columbia College, and was president of the college from 1849 to 1864. Under his administration the school of medicine was reestablished and the school of mines organized. W S M

#### KING'S COLLEGE, LONDON, ENGLAND

— A constituent part of the University of London (*q v*), founded in 1829 "for the purpose of giving instruction in the various branches of literature and science and the doctrine and duties of Christianity as the same are inculcated by the United Church of England and Ireland." The Duke of Wellington was an ardent supporter of the college in its beginnings. Work was begun in 1831, and in 1836, when the University of London was founded, King's College became a constituent body. To the departments of literature and science a medical department was soon added; an engineering department followed in 1838; a hospital in 1839, theology in 1847, evening class in 1856; an oriental section in 1861, the woman's department in 1881. In 1903 the obligation of membership of the Church of England for appointment on the teaching staff was removed completely, except in the faculty of theology. By act of 1908 the departments of theology and advanced medicine were placed under independent boards and King's College and the King's College for Women were incorporated in the reconstituted University of London, with the following faculties and departments: arts, science (natural and medical preparatory), engineering, evening classes, and teachers' training department. The institution has always been well attended and the enrollment in 1910–1911 was 3147 (1402 regular and 1745 occasional students).

**KINGSBURY, JOHN** (1801–1874) — Leader in the movement for the organization of high schools for girls; was born at Coventry, Conn., on May 26, 1801, and graduated from Brown University in 1826. He taught for two years in the schools of Providence, and in 1828 he organized the Providence Young Ladies' High School, which he conducted for many years. He was one of the founders of the American Institute of Instruction (*q.v.*) and of the Rhode Island Institute of Instruction, and from 1857 to 1859 he was State Superintendent of schools in Rhode Island. **KINGSLEY, CHARLES** (1819–1875) — The English clergyman, poet, and novelist was born at Holne, Dartmoor, and educated privately and at King's College, London. He entered Magdalene College, Cambridge, in 1838, was ordained in 1842, and in the same year he became curate of Eversley which practically became his home until his death. He was for a year, Professor of English Literature and Composition at Queen's College, Harley Street, London, under F. D. Maurice (*q v*), and in 1860 became Professor of Modern History at Cambridge. In his own parish he took a deep interest in the education of his people and established an adult school, a writing school for girls, and an infant school. He is, however, associated mainly with the Christian Socialist Movement, which he espoused in 1849, stirred by the sufferings of workmen throughout the country. Under the name of "Parson Lot" he wrote "Letters to the Chartist" in *Politics for the People* and the *Christian Socialist Cheap Clothes and Nasty* exposed the evils of the sweatshop, and the novels, *Yeast* and *Alton Locke* placed before a larger public the social questions of the day. His interest centered in "national education, sanitary and dwelling-house reform, the free sale of land and corresponding reform of the land laws, moral improvement of the family relations, public places of recreation." As a member of the Educational League he strongly advocated a national and comprehensive system of education and supported W. F. Forster's Bill (1870). In 1869 he delivered a presidential address on education, "female and male, compulsory and for all charges," before the Social Science Congress at Bristol, which was published and widely distributed. Like his friend, Maurice, he sympathized strongly with the movement for the higher and professional education of women. In *Health and Education*, a collection of various essays (1874) Kingsley dwells on the value of a knowledge of hygiene and sanitation and on the importance of science. *Alexandria and her Schools* (1854), is a collection of four lectures dealing with the rise, development, and decline of different systems of philosophy from the Ptolemaic era onward, and it was with one phase of this that the novelist dealt in *Hyppatia* (1853). It is perhaps in the field of children's literature that Kingsley's contribution has been greatest and will be more enduring. His earliest work for children was *Glaucus or the Workers of the Shore* (1855), which like *Madam How and Lady Why* were intended to interest children in science. *Heroes or Greek Fairy Tales* (1856), *Water Babies* (1863), and *Hereward the Wake* (1866) are beautiful stories which will always continue

to make their appeal to readers both young and old.

**KINNER, CYPRIAN** -- A Silesian described by Samuel Hartlib as "of a very public spirit to advance that part of learning which is the foundation of all the rest, *i.e.* the right education of children." Kinner was born and educated in Silesia, and married a rich wife, from whose estate £2600 was set apart to develop his educational plans. But the imperial troops entering Silesia, he and his wife were driven into exile in Transylvania and Hungary, where he met Alsted. Kinner then came into communication with Comenius, and went to meet him in Prussia. Comenius was called away to Lessna, and Kinner was left at Dantzic "to depend upon Providence." He was anxious to devote himself entirely to educational plans, but had no funds even for subsistence. Samuel Hartlib translated the Latin draft of Kinner's educational tract, and published it in London c. 1648, under the title *A Continuation of Mr John Amos Comenius's School Endeavours, or a Summary Delineation of Dr Cyprian Kinner Silesian, his Thoughts concerning Education*. The title is interesting as anticipating that of John Locke. He aims at three "marks": Piety, Learning, and Civil Prudence. His main position for early teaching is realistic and is stated as follows: "I show Naturall Things in the living book of Nature, Things Artificiall in the Shops and Work-houses of their Makers, and both of them in the Repositories of their figures and representations, which belong to our School, where I show them either *living* or carved (vet as near the life as may be) or at least painted." Kinner is thus a follower of Lubinus (*q.v.*), as well as of Comenius, and appears to go even farther in the suggestion that "animals should be provided and kept for the purposes of school teaching." **KIRCHENORDNUNGEN** -- The laws or regulations for the government of the evangelical churches of Germany, issued by the rulers of various states, often with the advice and consent of the orders or estates. While there were *Kirchenordnungen* before the Reformation, the sixteenth century is the period in which most of them appear. Through these

regulations the old laws were modified to meet Reformation ideals, and the maintenance of proper administration of teaching and sacraments was secured. Without some such laws an apparently impossible condition would have had to exist: the free development and administration of church and school laws upon the basis of the Lutheran ideal without the sanction of any responsible and efficient administrative body. While these *Ordnungen* were generally promulgated by the secular authority, they were largely the work of clergymen and teachers. Melanchthon, Luther, Bugenhagen, Joannes Aepin, Urbanus Rhegius, and many other prominent men of the time lent their assistance. Luther was the author of the Wittenberg *Kirchenordnung* of 1523 and collaborator in several others. Melanchthon was concerned in the writing of at least nine *Ordnungen*, beginning with Nuremberg (1526) and the Saxony Visitation Articles (1528). When once a few typical *Ordnungen* had been framed, they were adopted as models. Thus the Saxony Visitation Instructions became the basis of the Brunswick *Kirchenordnung* (1528), and upon the latter were based those of Hamburg (1529), Lubeck (1531), Pomerania (1535), Schleswig Holstein (1542), and many others, including that of Wittenberg (1533). This Wittenberg *Ordnung* in time became the model after which at least seven others were composed.

While the *Ordnungen* are not uniform in their material or arrangement, there is at least a general similarity in subject matter. As a rule there is a first part, called *Credenda*, which is dogmatic in its nature and is an expression, in more or less definite form, of the agreement of the city or provincial church with the general Lutheran confession of faith. This is followed by the *Agenda*, which contains provisions concerning liturgy, appointment of church officers, duties of officers of church and school, organization of church government, discipline, administration of church property, care of sick and poor, baptism, and miscellaneous matters relating to church affairs. **KITCHEN GARDEN** — The Kitchen Garden is a method of teaching little children household processes through songs and games with an equipment designed for the purpose. This method was devised by Miss Emily Huntington (d. 1910), who directed a mission school for girls on the East Side of New York City more than thirty years ago. A visit to a kindergarten exhibition gave her the idea that children might be taught housework through games. She wrote the songs and games, which were afterward published in book form. She began by using toys as they were found in the market, and later found manufacturers who made articles designed for this purpose. Classes were formed in the Wilson Mission by a number of young women interested in the work of teaching these children. The Kitchen Garden Association was formed in 1880 to promote the teaching of industrial and domestic arts, enrolling eighty active members and supervising the instruction of nearly a thousand children in and near New York. Classes were formed in the West and South. The Kitchen Garden Association was reorganized as the Industrial Educational Association (See HOUSEHOLD ARTS.) Miss Huntington also devised a series of lessons in cooking taught in the same way and published a volume of these lessons. The toys were copyrighted.

The Kitchen Garden system is still used in Settlement work in New York City to some extent, and for the same purpose in other parts of the country, but it has never become incorporated in the public school system. The work is being continued by Miss Peck of New York, whose method is now being used in Los Angeles, Washington, D C., and New York.

H K

**KLAUSENBURG (KOLOZSVÁR), THE ROYAL HUNGARIAN FRANCIS JOSEF, UNIVERSITY OF.** — The youngest of the

three Hungarian universities (the other two being Agram and Budapest), established in 1872. The university maintains faculties of law and political science, medicine, philosophy, and pure science, there being no school of divinity. The great majority of the students (1497 out of 2116 matriculated students in 1909-1910) are enrolled in the faculty of law, medicine following with 321, and philosophy and pure science bringing up the rear with 298, 191 auditors bring the total attendance of the year in question to 2307. The annual budget amounts approximately to \$415,000. The library, founded in 1872, contains 200,000 volumes. Associated with the university is a Unitarian theological faculty, established in 1556, and a reformed theological academy, founded in 1895. Klausenburg is also the seat of an agricultural school, originally established in 1869 and reorganized in 1906. R T, Jr.

**KNIGHT, EDUCATION OF THE.** — See CHIVALRIC EDUCATION, GENTRY AND NOBLES, EDUCATION OF, MANNERS AND MORALS, EDUCATION IN.

**KNOWLEDGE.** — A term of the very widest scope, designating, as will presently appear, a variety of operations and of subject matter that, however, possess at least two elements in common, namely, some connection direct or indirect with intelligence (or reflection) and with certainty, security, assurance, settledness. Like many analogous terms, — conception, judgment, thought, for example, — the term has both an active and a passive sense; it designates both an operation or act, that of knowing, and the result, what is known. Like the term "science," however, the word "knowledge" is itself used mainly in a passive sense to denote the content, the subject matter, which is the outcome of the successful performance of the function of knowing. The verb "to know" and the participle "knowing" retain both

senses, designating the act of inquiry, search, finding out, and also the possession of a certain subject matter. The opposite of knowledge is ignorance.

The term "knowledge" covers four distinct connected matters. Of these the two first to be mentioned are the most personal, direct, and practical. They are knowledge in the sense of intelligently acquired skill, and in the sense of acquaintance. We know *how* to walk, talk, skate, etc.; experts know how to weave, dye, work metals, etc. Ability to do things is perhaps the most primary sense of knowledge. The ability is distinguished from instinct only in that it has been intelligently acquired. But even this difference is not consistently maintained, for we speak, popularly, of an instinctive knowledge. The first necessity of a living being is to know how to conduct itself with respect to certain situations; in order to live it must be able to adapt its behavior to the behavior of the things with which its own fortunes are bound up. This necessity includes not only physical needs, but also the fundamentals of social intercourse and the elements at least of some of the social arts. The primary and profound character of this sort of knowledge is seen in the fact that until the rise of philosophy among the Greeks the same word denoted art (technical skill) and knowledge, namely, *τέχνη*. The well-known recourse of Socrates to the analogies of the arts, his appeal to the procedure of the shoemaker, flute player, carpenter, etc., in his logical discussions was witness to the fact that the control of his material evinced by the artisan in reaching the ends appropriate to his art represented at once the most certain and the most intelligent procedure extant.

Familiarity, acquaintance, are closely connected with knowing how to do, and to a considerable extent they result from the latter and measure its extent. So far as we can adapt ourselves readily and successfully in any situation, we are familiar, acquainted. The rough edges of a strangeness, remoteness, the barriers of understanding nothing, are worn away. In their place there is a sense of intimacy, of inner adjustment. When we know how to behave with respect to a thing, we know what it is like; we are on terms with it; there is mutuality of response. Knowledge in the form of acquaintance is not only the outcome and reward of knowing how, or intelligent skill; but it establishes emotional ties—a capacity for appreciation, or apprehending the thing in terms of its worth, its usefulness for a purpose. Acquaintance, familiarity, normally presuppose a certain amount of friendliness, of agreeableness, as well as a sense of power and ease. But excessive familiarity, too long continued occupation with one subject, "breeds contempt", it leads to revulsion, a sense of ennui and constraint.

Our third sense of knowledge covers that

acquired from others, that attained indirectly by learning from others. Communication by means of language carries us far beyond the limits of personal acquaintance with persons and things, leading us to know *of* or *about* many matters which are within the direct acquaintance of other people. By oral tradition and more especially by written and printed language, this second-hand knowledge comes to include much that is not and that could not be within the direct acquaintance of any living. Such knowledge constitutes information (*q v*) and also learning—in the sense of what is learned or is to be learned.

In all the three above-mentioned types of knowledge, intelligence or reflective thought is used, but only secondarily. It is employed as a means of gaining control of things, in enlarging acquaintance with them, in apprehending and understanding things reported by others. It is not, however, used in any sense as a source of knowledge for its own sake. Gradually, however, materials of acquaintance and of information are amassed and systematized not for the sake of increasing familiarity and possession of learning, but for the sake of rational demonstration or of inferential discovery of new knowledge. Men are not contented with the kind of assurance that rests upon personal acquaintance or upon the credit of others, they search for that which opens from rational grounding, from logical sequence and system. Thus a fourth kind of knowledge comes into existence: rational knowledge, science, knowledge *that* so and so is true. Like information, this sort of knowledge is indirect, but it is indirect in the sense of dependence upon logical data and premises, not in the sense of dependence upon the observations and reports of others. From this point of view, knowledge is identical with *science*, and we have no logical right to denominate intelligent skill, matters of acquaintance, of information, *knowledge*, unless they are reduced to general principles and are connected with one another in systematic ways. Otherwise they represent beliefs, opinions, rather than knowledge. This tendency to define knowledge from an exclusively logical point of view has been an important factor in calling out in reaction the philosophy of pragmatism (*q v*), which regards this exclusive view of knowledge as the characteristic error of intellectualism (or rationalism, as it is sometimes termed). The purely technical character of knowledge when defined on a purely logical basis, its aloofness from practical considerations, from the affections and aversions (so important a factor in acquaintance) and from the social processes of learning and transmission characteristic of information, are treated as evidence that scientific knowledge, when isolated, is an abstraction. Thus the other types of knowledge are regarded as not only more primitive genetically and psychologically (which would be generally admitted), but also as more final and

significant. In fact, knowledge as a system of logical propositions is regarded by it as ultimately of value because of the greater control and the greater richness of content that it supplies to the more direct, active, and social types of knowledge

Educationally speaking, there can be little doubt that the order in which the four types of knowledge have been set forth in this article represents the order of their development. The opposition of all modern educational reforms to beginning with so-called "deductive" methods, with systems of definitions, classifications, and laws of explanation, is, in substance, a claim that the logical type of knowledge represents a matured, relatively late specialized development of more basic bodies of knowing, and is consequently meaningless and educationally harmful when presented in isolation or as a starting point. On the other hand, many of the reformers have, in their reaction against abstractions in education, failed to note the operation of a subordinated factor of reflection and interpretation in even the more primitive modes of knowing, and have thus made the mistake of identifying the "concrete" with the bare physical object, instead of with the center of an active experience, or interest.

Many questions of instruction are bound up also with the matter of the relation of information or communicated knowledge, to personal acquaintance. A flavor of the second-handness, derived, and more or less conventional hangs about information. Its subject matter is not so vitally lived through, so intimately appreciated, as that of familiar acquaintance. Any examination of prevailing modes of instruction will show that the mere bulk of matter communicated in books and lectures tends to swamp the native and active interests operative in intelligent behavior and in the acquaintanceship it brings. Then this matter remains unassimilated, unorganized, not really understood. It stands on a dead level, hostile to the selective arrangements characteristic of thinking, matter for memorizing, rather than for judgment, existing as verbal symbols to be mechanically manipulated, rather than as genuine realities, intelligently appreciated. Yet without this communicated matter, the circle of personal acquaintance is very narrow and superficial, and personal activity hardly gets above the place of routine. The solution is found in realizing that social communication is a very real factor in personal doing and acquaintance. The educational aim is not to multiply information for the sake of information, nor yet to try to exclude it or narrow it down as much as possible. It is to fuse the transmitted matter and the matter of direct behavior and emotional response with as intimate union as possible, so that the former will gain force, vivacity, directness from the latter, while the former is insensibly but continually extended and deepened by the latter.

In short, the common error does not consist in attaching great importance to transmitted facts and ideas, but in presenting them in such an isolated way that they are not spontaneously welded with the intense, though narrow, matters of direct concern. J. D.

**KNOX COLLEGE, GALESBURG, ILL.** —

A nonsectarian, coeducational institution, incorporated as Prairie College in 1836, had its inception in the plan of the Rev. George W. Gale, a Presbyterian clergyman, to found a college in the Middle West. In 1837 the institution was chartered as the Knox Manual Labor College. The name was changed to Knox College in 1857. The Lincoln-Douglas debate of 1858 was held on the grounds of the college. Distinguished presidents have been Jonathan Blanchard (1845-1856) and Newton Bateman (1876-1893), educational leaders in Illinois, and John Huston Finley, '87, who in 1903 became president of the College of the City of New York (*q.v.*). Knox College is one of the institutions originally accepted by the Carnegie Foundation for the Advancement of Teaching (*q.v.*). The Board of Trustees is a body of twenty-five members selected by a committee of the trustees on whose recommendation the board acts, the term of service is for life. By resolution of the board no denomination can have a majority of trustees.

Knox College maintains undergraduate courses leading to the A.B. and B.S. degrees. The entrance requirements are fourteen units. A conservatory of music was organized in 1883. The degrees of A.M. and M.S. are given for one year's graduate study in residence.

There was in 1910-1911 a faculty of twenty-five members and an enrollment of 616 students, of whom 335 were in the collegiate department. C. G.

**KNOX, JOHN** (1505-1572) — The great leader of the Scottish Reformation, and deviser of the *Book of Discipline*. The date of his birth is uncertain, for though the traditional date is 1505, yet there are implications from contemporaries that seem to point to the limits of 1513-1515. Knox is thought to have been born in Giffordgate, a hamlet adjacent to Haddington in Scotland. It is assumed that he was educated at Haddington Grammar School, and entered St. Andrews University in 1529, where he studied the ancient fathers, particularly St. Augustine (*q.v.*), a fact which explains his "preparedness" for the doctrines of Calvin (*q.v.*) later on. By 1540 he had become a priest of the Church of Rome, exercised

the office of notary, and for a time was a private tutor. It was not till 1545 that he showed any signs of becoming a Protestant. Knox came to England, and was sent by the Privy Council as Protestant Minister to Berwick-on-Tweed, where he stayed for two years, with a congregation consisting of the garrison and citizens. In 1551 he was removed to Newcastle-on-Tyne, and was appointed a royal chaplain, and had the offer of the bishopric of Rochester, which he declined. In 1554, when Queen Mary had already begun her policy of persecution, Knox left England, and after a tour through Swiss Protestant congregations, he reached Geneva and entered into friendship with John Calvin. From 1554 to 1559 Knox remained on the Continent. He became one of the two ministers of the English Protestant refugees at Frankfurt in November, 1554. Here internal dissensions took place with regard to the use of the English Prayer Book, and Knox voluntarily retired to Geneva in 1555. The complete supremacy of Calvin in Church and State made a most imposing object lesson in theoretical government, one not lost on Knox, whose *Book of Discipline* was afterwards closely framed on the Genevan model. His theological views were definitized by his treatise on *Predestination* published in 1560. Knox's permanent return to Scotland was in 1559. He was appointed minister at St. Giles' Church, Edinburgh, and soon became the leader of the Scottish Reformation. In 1560 the Estates demanded a statement of the views of those who opposed Roman Catholic doctrine, and to Knox and five others was intrusted the drawing up of the *Confession of Faith*. Penal statutes were then granted against the saving of mass. In 1560 the organization of the Reformed Church was laid down in the *Book of Discipline*, which was drawn up by Knox and the other five ministers who had composed the *Confession of Faith*, and was translated into Latin, so as to obtain the criticism of Calvin and the Swiss Reformers. Knox brought Geneva and Calvin to Scotland and acclimatized them to Scotch soil. The Ecclesiastical polity carried with it, as was the case at Geneva, the educational system, and this, again, was of the most democratic type.

The chapter in the *Book of Discipline* devoted to schools could not be carried out without a large sum of money, and though the Scottish reformers proposed to appropriate the money for this purpose from the old ecclesiastical revenues, the Scottish nobles, as had been the case with the English nobles, hoped to get a share in the plunder. Their success necessarily deferred the carrying out of such a scheme into immediate execution. The *Book of Discipline*, however, did not receive the sanction of the Scottish Parliament, and Scottish education was not endowed with Roman spoils. Nevertheless, the educational ideals of the *Book of Discipline* mark an important stage

in the history of education, for they suggest a deliberate scheme of organization of national education. The salient educational features of the *Book of Discipline* together with the steps in the actual development of the Scotch educational system are presented in the article on SCOTLAND, EDUCATION IN.

The later years of Knox's life (1560-1572) were concerned with the political and religious questions centering round the names of Mary, Queen of Scots, and (afterwards) of the regent, the Earl of Moray. Politically, in the days of the Tudors, he was prepared to advocate the deposition of tyrants, and thus is a predecessor of the spirit of a Cromwell. Religiously, Knox put Scotland in touch with the religion of Geneva, of the Huguenots, and the Dutch, and thus tended to help forward cosmopolitan sympathies, at least, amongst Protestants in Great Britain and abroad. His democratic tendencies are shown in laying the basis of Scotch Presbyterianism, in the introduction of lay elders and deacons into church government. It is not too much to say that these characteristics, though not technically educational, have had great educational effects.

**KNOX, VICESIMUS** (1752-1821) — English schoolmaster and essayist, born near

London. He was educated at Merchant Taylors' School and St. John's College, Oxford, graduating B.A. in 1775 and obtaining a fellowship. In 1778 he succeeded his father as headmaster of Tonbridge School, a position held up to 1812. He devoted himself to miscellaneous essay writing, *Winter Evenings or Lucubrations on Life and Letters, Essays Moral and Literary, Family Lectures or Domestic Divinity* and several other works of a religious nature. For his school he edited Catullus, Horace, and Juvenal, and *Elegant Extracts, or Useful and Entertaining Passages in Prose, selected for the Improvement of Classical and Other Scholars in the Art of Speaking, in Reading, Thinking, Composing, and in the Conduct of Life* (1785), *Elegant Extracts or Useful and Entertaining Pieces of Poetry selected for the Improvement of Youth* (1789), *Elegant Epistles or a Copious Collection of Familiar and Amusing Letters selected for the Improvement of Young Persons and for General Entertainment* (1790). His treatise, entitled *Liberal Education or a Practical Treatise on the Methods of acquiring Useful and Polite Learning* in two volumes (1781), is a valuable contribution to the history of education. It not only contains sound criticisms of existing practice with suggestions for reform, but a good account of the best textbooks of the period. While insisting on thorough classical curriculum as the only means of educating gentlemen, Knox would admit such studies as English, French, geography, history, and the elements of Euclid. The modern languages are to be taught on the same method as the classics, that is, grammatically, although he recommends broad reading in English literature both in and out of school. Accomplishments and athletics are advocated, provided that they do not become distracting. Examinations are to be held frequently as a method of retaining what has been learned. Knox recognizes that women are intellectually as capable as men and would have them educated privately (for boys the public schools were best) in English and French, the classics being added, if they have inclination and wealth. The second volume deals with the universities and gives a very good insight into the corruption and lack of discipline there prevailing. Knox attacks conservatism, formality in trifles, absence of study, and idleness of the professors and fellows, who regard the universities not as places of education but as almshouses. The remedy according to Knox is greater emphasis on study and less on formalities supervised by the proctors. In 1821 Knox wrote *Remarks on the Tendency of Certain Clauses in a Bill now Pending in Parliament to degrade Grammar Schools, with Cursory Strictures on the National Importance of preserving Inviolable the Classical Discipline prescribed by the Founders*. The pamphlet was called forth by a Bill to introduce into the old foundations

instruction in reading, writing, and arithmetic for poor children.

**KNOXVILLE COLLEGE, KNOXVILLE, TENN.** — A coeducational institution for the education of negro youth under the auspices of the United Presbyterian church opened in 1875. The following departments are maintained: collegiate, normal, theological, musical, industrial, and common school. The entrance requirements to the college, which offers courses leading to degrees, are about fourteen points of high school work. Of the 404 students enrolled in 1909-1910, only 29 were in the collegiate department. There is a faculty of thirty-four members.

**KOBEL, JAKOB** (1470-1533) — One of the most prominent of the early German writers on arithmetic. His name also appears as Kobel, Kobelius, and Kobilius. He was born at Heidelberg in 1470, and died at Oppenheim, January 31, 1533. He was a fellow student of Copernicus at Cracow. He was a man of varied attainments, meeting with success as a *Rechenmeister*, printer, engraver, woodcarver, poet, and public official. He wrote three works on arithmetic that met with great favor: (1) *Ain New gemdnet Rechenbuechlin*, Augsburg, 1514, (2) *Mit der Kynde od' Schriebsfedern*, Oppenheim, 1520, (3) *Vysierbuch*, Oppenheim, about 1515. The third related to gauging, at that time a very popular subject. The first of these books was purely commercial, and the operations on numbers were performed by means of counters, as was then the custom. Roman numerals are used practically throughout the work, even in writing common fractions, where  $\frac{II^c}{III^c \cdot LX}$  appears for  $\frac{200}{460}$ . His

work showed little Italian influence, and it is one of our best sources of information as to the early German arithmetic. D E S

**KONIGSBERG, THE ROYAL PRUSSIAN ALBERTUS UNIVERSITY OF** -- Founded by Margrave Albrecht, the last knight of the Teutonic Order in Prussia, who in 1541 established a university preparatory school, transformed into a university, of Protestant affiliations, three years later.

The new university secured a good start, notwithstanding financial difficulties, enrolling a considerable number of foreigners, principally from Poland, Russia, and Sweden. Its further development was sadly hampered, however, by the plague of 1549 and still more by the Thirty Years' War in the following century. For two centuries after its establishment its history is replete with theological controversies. The close of the seventeenth and the beginning of the eighteenth century marked an era of healthy growth, for which the Great Elector and the first kings of Prussia were largely responsible. The period of its greatest renown, however, came somewhat later in the days of Kant (*q v*), who became a docent at the university in 1755, and full professor of philosophy fifteen years later (1770-1797). One of his successors was J. F. Herbart (*q v*), who established a pedagogical seminar at Königsberg in 1810.

In 1862 a new main building was erected for the university, and for thirty years after the Franco-German War considerable activity was displayed in the building of laboratories and institutes of various kinds, including laboratories for agricultural chemistry and for dairying, and in 1901 a new library building containing almost 300,000 volumes and about 1500 manuscripts.

Among the prominent former members of the teaching staff may be mentioned Bessel in astronomy, Jacobi in mathematics, Hagen in natural science, Burdach in anatomy, Helmholtz in physiology, physics, and mathematics, Wagner in surgery, Karl Lachmann in Germanic philology, and Simson and Stobbe in jurisprudence. The German Crown Prince is rector of the university, a prorector being elected annually by the faculty. The annual budget amounts to about \$400,000. Through the initiative and financial assistance of Dr. Fritz Lange, a German physician who practiced for a number of years in New York City, the first German student "Union," the Palæstra Albertina, was established by the university in 1898. The building contains a gymnasium and a refectory, clubrooms, fencing rooms, swimming pool, etc., but owing to the lack of sufficient endowment, provision has been made in it since 1905 for several university seminars.

In size Königsberg ranks fifteenth among the twenty-one German universities. In the winter semester of 1911-1912 there were in attendance 1694 students, of whom 199 were auditors. By faculties the matriculated students were distributed as follows: philosophy 701, medicine 432, law 280, theology (Protestant) 92. The teaching staff consisted of 91 professors and 57 docents.

The city of Königsberg is also the site of a royal academy of art, established in 1845 and reorganized in 1901.

The municipal library was founded in 1540

and contains 50,000 volumes and over 600 manuscripts.

R. T., JR.

**KRAKAU, THE UNIVERSITY OF, KRAKAU, AUSTRIA.** — One of the oldest universities in Europe, the papal bull providing for its establishment having been signed by Pope Urban V on May 12, 1364. No provision was made in the deed of foundation for a theological faculty, and six years after its foundation the university was compelled to close its doors. Permission to establish a faculty of theology was granted by Pope Boniface IX in 1397, and three years later the university was reorganized by King Wladislaw Jagello of Poland, being removed to a new site in the following year. Krakau being the capital of Poland from 1320 to 1610, the university served for several centuries as the center of the intellectual life of the Kingdom of Poland. Gradually, however, after the Polish capital had been transferred to Warsaw at the beginning of the seventeenth century, a decline set in and led finally to another reorganization in 1817. In the meantime, at the last partition of Poland in 1795, Krakau had been turned over to Austria, becoming part of the free state of that name thirty years later. In 1846 Austria again assumed control, and since then the development of the university has been marked by continuous progress. The German language was used in all faculties, with the exception of the theological, from 1853 on, but has been gradually supplanted by Polish, which has reigned supreme since 1870.

The university library was founded in 1400 and contains over 400,000 volumes, over 6000 manuscripts, over 3000 maps, and almost 10,000 engravings and other reproductions. It is housed in the old university building, which was completed in 1497, but altered and repaired at various times between 1839 and 1872. The new main building was erected in 1881-1887. The annual budget of the university amounts to approximately \$225,000. Krakau is the third largest university in Austria, being exceeded in point of attendance only by Vienna and Budapest. In the winter semester of 1909-1910, there were enrolled 3211 students, including 441 auditors, of whom 209 were women. Of the matriculated students, 1307 men were registered in the faculty

## KRAUS

of law, 446 men and 48 women in the faculty of medicine, 701 men and 182 women in philosophy, and 86 men in theology (Catholic)

Krakau is also the seat of an art academy, established as an art school in 1818 and transformed into an academy in 1900. Here, also, Polish is the language of instruction

**KRAUS, JOHN** (1815–1896) — Active in American kindergarten work. He was educated in the normal schools of Germany, and after coming to America was engaged in private and public school work, and from 1867 to 1873 he was connected with the Bureau of Education of the United States. In 1873, with his wife (Maria Kraus-Boelte), he organized a training school for kindergartners in New York City. His published writing includes several papers on the kindergarten. W. S. M.

**KRUSI, HERMANN, JR** (1817–1903) — American Pestalozzian, born at Yverdon, Switzerland, on June 24, 1817. He received his education in the cantonal schools at Trogen, the normal school at Gais (conducted by his father), and at the normal school at Dresden, conducted by Dr. Blochmann, afterwards minister of public instruction of Saxony, and at one time an associate of Pestalozzi in the institute at Yverdon. After an additional year of inspection of the normal schools and other institutions of Germany, he returned to Switzerland and taught for five years in the cantonal normal school at Gais under the principalship of his father (1841–1846). In 1846 he received an appointment as instructor in a Pestalozzian school at Cheam, England, organized by Charles Mayo (*qr*). The school was Pestalozzian in name only, notes Krusi, for its methods were relics of the medieval age. At the end of the year he severed his connection with the school at Cheam to accept an appointment in the normal college conducted by the Home and Colonial School Society (*qr*). He had charge of the classes in methods of teaching, mathematics, and drawing, and while here he worked out and published his system of inductive drawing. After five years (1847–1852) in the normal college in London, he returned to Switzerland, but a year later he came to America to accept a post in the private normal school conducted by William Russell (*qr*) at Lancaster, Mass. Here his associate teachers were Dana Pond Colburn and Sanborn Tenney. He was institute lecturer in Massachusetts for two years (1855–1857), having as associates his country-

## KRÜSI, HERMANN, SR.

men Louis Agassiz and Arnold Guyot (*qqv*). For two years he was associated with W. F. Phelps (*qr*) in the newly organized state normal school at Trenton, N. J. (1857–1859). The next three years were devoted to lecture work in Massachusetts, and in 1862 Mr. Krusi accepted an appointment in the state normal school at Oswego, New York, with Dr. E. A. Sheldon (*qr*), where he spent twenty-five active years in the work of training teachers. He was one of the principal figures in the Oswego movement (*qr*) which emphasized oral methods of instruction in primary schools. He resigned his post at Oswego in 1887 and spent his closing years at Alameda, California, where he died on Jan. 28, 1903. His published writings include a *System of Inductive Drawing*, published originally in England and republished in the United States, *Life, Work, and Influence of Pestalozzi*, *Recollections of my Life*, and various essays and addresses on the philosophy and history of education.

**KRUSI, HERMANN, SR** (1775–1844) — Swiss educator and first associate of Pestalozzi, educated in the schools of Gais in the canton of Appenzell. He taught in the public schools of Appenzell from 1793 to 1799, when he took charge of an orphan school at Burgdorf. It was here that he made the acquaintance of Pestalozzi. After a short time Krusi united his school with that of Pestalozzi, and he accepted the rank of assistant teacher. Three of Krusi's friends, Tobler, Niederer, and Buss, were called to the Burgdorf institution as additional assistants. The four men had previously arrived at ideas similar to those held by Pestalozzi. They were devoted to, and believed in, disseminating his ideas. They lived under conditions of great poverty, simplicity, and even ignorance, but they lived in an atmosphere of human love. In his *Recollections*, Krusi says that his life at Burgdorf was broadened, deepened, and enlightened. When Pestalozzi transferred his institution to Yverdon in 1805, he was accompanied by Krusi. He continued to labor here until 1816, when there arose serious differences among the associates of Pestalozzi because of the arrogant demeanor of the financial manager of the school, Joseph Schmid (see PESTALOZZI). Krusi, Tobler, Buss, Niederer, and the other trusted associates of the great Swiss reformer resigned in a body, and Krusi organized a private school at Yverdon which he conducted for six years. In 1822 he was called to the

principalship of a higher cantonal school at Trogen. Under his administration the school attained distinction, and pupils were sent to it from different parts of Switzerland and from Italy. In 1833 Krusi was called to the principalship of the new normal school at Gais. The school became well known in Europe, and was visited by many American and English students of education who have left records of their impressions. It was in many important features a replica of the more famous institution at Yverdon. Books, except for reading, were seldom used. The instruction was largely oral, but the pupils had to make their own books, by collecting and organizing the subject matter of class exercises into notebooks. Field excursions for the purpose of studying natural history and local geography occupied considerable time, and walking, climbing, swimming, and systematic exercises in gymnastics formed a part of the physical training of the students. He continued at the head of the cantonal normal school at Gais until his death in 1844. His son, Hermann Krusi, Jr. (q v), was first a student and later an instructor in the normal school at Gais. W. S. M.

**LABORATORY** (from Lat. *laborare*, to labor) — Originally the term applied to the shop where the alchemist or chemist elaborated his chemical and medicinal products, now used very generally to indicate the buildings or rooms set

apart for conducting practical investigation in any of the sciences. The laboratory furnishes a most important adjunct to any educational institution and is essential in the teaching of any science, and is treated in its various aspects under different captions in the Cyclopaedia. The theory of laboratory work is discussed under EXPERIMENT, EXPERIMENTATION, LOGIC OF, EXPERIMENT IN EDUCATION, EXPERIMENT, TEACHING BY, also PSYCHOLOGY, EXPERIMENTAL, SCIENCE, EXPERIENCE, and EMPIRICISM. The function, equipment and operation of laboratories is discussed under each of the natural sciences, as BOTANY, CHEMISTRY, PHYSICS, etc. Of special educational interest is the treatment under EXPERIMENTAL PEDAGOGY, PSYCHOLOGY, EDUCATIONAL, PSYCHOLOGICAL LABORATORY. In a broader, less technical sense, the term is sometimes used to refer to such work as is described under EXPERIMENTAL SCHOOLS and STATISTICAL METHOD. The literature of the subject will also be found in connection with the articles mentioned above. The historical development of the laboratory is outlined in the historical sections of the articles on the various natural sciences.

**LA CHALOTAIS, LOUIS RENÉ DE CARADEUC DE** (1701-1785) — French magistrate and statesman. He was a striking figure during the pre-revolutionary period, and one who exerted a noteworthy influence on the educational thought of his time. His *Two Reports on the Constitutions of the Jesuits* submitted in December, 1761, and May, 1762, to the Parliament of Brittany, of which he was Attorney-general, were largely instrumental in bringing about the suppression of the order in France (1764). Falling into disfavor, he was thrown into prison, and there in solitary confinement wrote a remarkable defense, closing with these words: "Written with a pen fashioned from a toothpick and in ink made from a mixture of chimney soot, vinegar, and sugar, on the paper wrappings of packages of chocolate." "The writings of La Chalotais," said Voltaire, "will live forever." The most important work of his life was probably his *Essai d'Éducation nationale ou Plan d'Études pour la Jeunesse* (1763), whose significance has unfortunately been almost completely overshadowed by Rousseau's *Émile*, which appeared in the previous year. This memoir, looking to the reform of the secondary education of his time, was almost immediately translated into Dutch, Russian, and German. He proposed to sub-

stitute for an educational scheme that was primarily adapted for purely school purposes, one that should fit the individual to discharge the duties that devolved upon him as a citizen. After a general introduction on the function of education, the inadequacy of the existing institutions, and the characteristics of the teacher, he laid down general principles for fixing the number of colleges (*i.e.* secondary schools), discussed some general considerations of method, and closed with a carefully elaborated curriculum for the secondary schools. In many of his arguments, especially those on the importance of the place occupied by physical education, on the practical value of modern language study, and on substituting lay teachers for the omnipresent clerical teachers, he was unquestionably far in advance of the prevailing practices of his time. **LACHMANN, KARL** (1793–1851) —

German scholar and critic, born at Brunswick. He was educated at home and in the local gymnasium, and in 1809 proceeded to the University of Leipzig with the intention of studying theology. He transferred, however, to classical studies which he pursued under Heyne (*q.v.*) at Göttingen, and under Beneke's influence he took up German philology. He took his degree at Halle. After teaching for a time at Berlin and Königsberg, he became professor extraordinary at the University of Königsberg and lectured on German philology. In 1825 he was called to Berlin, and in 1830 became a member of the Academy of Sciences. He edited numerous works in Greek, Latin, and German literature, and introduced new conceptions and new standards in textual criticism. The text, the author, the content and spirit of the work, were all to receive consideration. It was, however, on the purity of the text and the restoration of the original which claimed his chief attention. Among the chief of his editions are those on Propertius (1816), Propertius, Catullus, and Tibullus (1829), *Fables of Avianus and Babrius, Lucretius* (1845–1850), Greek Testament (the introduction containing an exposition of his views on textual criticism, 1850). Lachmann also wrote on meter in Greek poetry, on the dialogue in Greek Tragedy, and edited many early German works. Applying the principles of Wolf's *Prolegomena*, he tried to prove that *Die Nibelungen Not* could be dissected into twenty original lays, and later he divided the *Iliad* into eighteen distinct lays. Of Lachmann's influence Munro says, "Hardly any work of merit has appeared in Germany since Lachmann's *Lucretius* in any branch of

literature without bearing on every page the impress of his example."

**LACROSSE** — A game which had its origin with the American Indians under the name of "Baggataway." It was played by two sides, each consisting of a whole tribe, often numbering hundreds of players. The match was started at dawn and continued until one side had scored 100 goals, this often required several days of play from dawn until sunset with a few short periods of rest. From this crude game of battle, the Indians and the white inhabitants of Canada developed the modern game. The number of players was limited to twelve on each team, the size of the playing field decreased to about 125 yards by 50 yards, the goal posts lowered to six feet, the size and shape of the "crosse" or playing stick fixed, and the old buckskin ball replaced by a hard, rubber ball. From Canada the game spread to the United States in 1867 and to Great Britain in 1877. Harvard was the first college to adopt lacrosse when a team was organized in 1881. Princeton, Columbia, New York University, and Yale soon followed, and the game has gained steadily in popularity with college and preparatory school students.

Lacrosse is a splendid game, the running, dodging, catching, and throwing the ball, serve to develop vitality, speed, agility, and self-control in a large measure. Few games offer as many opportunities for individual skill and team play as lacrosse. Students who are too small for football or rowing often develop into skillful players, for agility and skill are more desired than weight or strength. The game is intensely interesting to spectators and in every way is one of the best games played in the colleges and schools. G L M

**LACTANTIUS FIRMIANUS** (c. 250–325)

— The last of the Latin apologists, a pupil of Arnobius (*q.v.*). He made Cicero his literary and philosophical model with such success that he was known amongst the humanists as "the Christian Cicero." He attained such eminence as a teacher of rhetoric that Diocletian made him official professor of eloquence in his new capital of Nicomedia, which he intended to make the intellectual and political equal of Rome. Constantine chose him to preside over the education of his hen-apparent, Crispus, in which occupation he spent his closing years as

## LADY MARGARET HALL

**Trier** He was in no sense an original thinker, but is distinguished for his sound judgment and elegant literary style, the milky softness of which procured for him the name Lactantius. He was a thoroughly consistent example of a Christian philosopher and his writings contain much valuable information as to the ancient systems of Philosophy. His *Divine Institutions* was the first attempt at a systematic exposition of Christian doctrine in Latin. The latter part of his *Epitome* of this larger work is an admirable compendium of religious ethics. His treatise *On the Anger of God*, directed against the Stoics and Epicureans, in which he proves the divine character capable of righteous indignation, was highly praised by St Jerome. *The Workmanship of God* is a discussion of the anatomy of the human body and the nature of the soul in opposition to the Epicurean Philosophy. He adopts the Creationist view, affirming that the soul is the immediate workmanship of God without human cooperation. His book on the *Deaths of the Persecutors* is a résumé of the various persecutions from the time of Nero and is of prime importance to the historical student. His treatise on *Grammar* is lost.

## LAFAYETTE COLLEGE, EASTON, PA —

A Presbyterian college opened in May, 1832, under the presidency of Rev George Junkin, D D. A scientific school was established in 1865 through the liberality of Ario Pardee, Esq. The college department now maintains three courses of study, Classical, Latin Scientific, and General Scientific, leading to the degrees of A B, Ph B., and B S., and the technical school courses in civil, mining, electrical, and mechanical engineering, and analytical chemistry leading to the appropriate degrees. The entrance requirements are fifteen units. The faculty (1911) consists of fifty members and the students number 560, — 286 in the college, and 254 in the technical school, with twenty pursuing graduate studies. The college is beautifully located at the junction of the Lehigh and Delaware rivers. The grounds occupy sixty acres. The buildings number fifty. Among those who have given distinction to the college are Professor James H Coffin, LL D, author of *The Winds of the Globe*, whose discoveries as to cyclonic storms are the basis of the forecasts of the Weather Bureau, and Professor Francis A March, LL D, L H D, D C L., who was one of the pioneers in the philological study of the English language. Ethelbert D Warfield, D D, LL D, has been president since 1891.

## LAKE FOREST COLLEGE

**LAGGARDS IN THE SCHOOLS.** — See RETARDATION, AND ELIMINATION OF PUPILS.

**LAKANAL, JOSEPH** (1762-1845) — French statesman, teacher, and, after Condorcet (*qv*), the most important of the educational leaders of the Revolutionary period. He was a member of the National Convention, and of the Council of Five Hundred. His position in educational history rests exclusively upon his activity as member of the Committee of Public Instruction in the former body. The bill, of which he was joint author with Sieyès and Daunou (*qv*), presented to the Convention, June, 1793, provided that the state assume the support of elementary instruction, and that secondary and higher education (barring some few subsidized higher institutions) should be left to private initiative. This bill shared the fate of so many of the projects of the Revolutionary assemblies and was set aside for another (the plan of Lepelletier). It was the report of Lakanal (February, 1795) that resulted in the foundation of the *Écoles centrales* (central schools), which bridged the gap in secondary education between the passing of the old régime and the establishment of the lycées by Napoleon in 1802. Lakanal's most distinctive work was his report (October, 1794) which provided for the foundation of the Normal School (see NORMAL SCHOOL, HIGHER). After the defeat at Waterloo, Lakanal came to the United States, where he spent some twenty-two years among his fellow countrymen in the south, residing at New Orleans for a part of the time. He returned to his native country in 1837, and there spent the remainder of his life.

pose of establishing a residence suburb and an educational institution within easy distance of Chicago. In 1865 the legal title of the institution became the Lake Forest University Collegiate work with a four years' course was not begun until 1876, up to that date a secondary education was provided for boys in the Lake Forest Academy, and for girls in Ferry Hall. Attempts were made from time to time to develop professional schools but in 1902 it was decided to confine attention to the development of the academic and collegiate departments only. The entrance requirements are sixteen units. The degree of A B is conferred on students who complete the required courses, which are arranged according to the group system. The A M is granted after a year of residence work and a thesis. In 1911-1912 there were enrolled in the college 185 students. The faculty consists of eighteen members.

**LALOR, THERESA** (1766-1846). — Founder of the first Roman Catholic school for girls in the United States. She opened a school for Catholic girls in Philadelphia in 1797. Two years later she took charge of the girls' school founded at Georgetown and in 1808 she became the mother superior of the Convent and Academy of Visitation. Five convents of her order were established in the United States. W S M

**LAMARCK** — See EVOLUTION, SCIENTIFIC THEORY OF

**LANCASTER, JOSEPH** (1778-1838). — The English educator and advocate of the monitorial system (*q v*). He was born in Southwark (London) on the 25th of November, 1778, the son of a small tradesman. Precocious piety and copious speech seemed to justify his parents' hopes that he would become a Dissenting minister, but he disappointed them by joining the Quakers, a sect without paid preachers. After being occupied for some time as usher, he (probably in 1798) opened a school on his father's premises. His enthusiasm and his natural aptitude for managing children combined with the food and clothes, which the benevolence of some Quakers enabled him to distribute during a severe winter, made his school so popular that it had to be transferred twice or thrice into larger rooms. Lancaster was nearly overwhelmed by his success. His pupils were too many for him to teach alone and he could not afford to pay for help. The idea, therefore, occurred to him of making those who knew a little teach those who knew less. Being entirely ignorant of the history of education, he thought that the idea was new, and he embodied it in a system of discipline and instruction showing considerable ingenuity. As he also invented sundry money-saving devices, such as substitutes for reading books and

copy books, he reduced the cost of maintaining a school.

Lancaster was so proud of his system that in 1803 he published *Improvements in Education as it respects the Industrious Classes of the Community, containing a Short Account of its Present State, Hints towards its Improvement, and a Detail of some Practical Experiments conducive to that End*. The fact that a second edition was published the same year proves the author's success in "pushing it." He had now begun to seek supporters outside the circle of his coreligionists. The earliest of his noble patrons were Lord Somerville and the Duke of Bedford, the most exalted was George III, with whom he procured an interview in 1805. The king listened patiently to a long account of the "System," expressed a wish that every poor child in his dominions should be taught to read the Bible, promised to subscribe a £100 a year, and put down the Queen for £50 and the Princesses for £25 each.

The royal favor expanded both the enthusiasm and the imprudence of Lancaster. He had already, with only a fraction of the cost assured, built a large schoolhouse in the Borough Road, he now added a printing press and a slate manufactory, he started a model rural school, and traveled in state to deliver lectures advocating the establishment of other schools. Toward the end of 1807 his debts were over £6000 and he was arrested. On Jan. 22, 1808, William Coiston, Joseph Fox, and he, meeting at Corston's house on Ludgate Hill, formed themselves into a "Society for the purpose of affording education to the children of the poorer subjects of George III" (See BRITISH AND FOREIGN SCHOOL SOCIETY). In July William Allen (*q v*) and others were added to the Committee. The members made themselves responsible for Lancaster's debts, undertook to manage his financial affairs, and released him for missionary journeys. As these resulted in the establishment of a good many schools, all requiring masters trained in the System, the business gradually grew too big for the original Committee, to which in December, 1810, more than forty noblemen, statesmen, and philanthropists were added.

In 1812 Lancaster, against the advice of his friends, started a boarding school in which his System was to be applied to secondary education. This was a private speculation which in a year brought him to bankruptcy. The institution in the Borough Road was not involved in his ruin, as the Committee, anticipating it, had induced him, for valuable consideration, to relinquish his legal title to the premises. In order to acknowledge his past services and provide for his future needs, the Committee created the post of superintendent of the schools with nominal duties and a liberal salary, but irritable vanity prevented his trying to cooperate with the men who had been

his generous and disinterested supporters, and in April, 1814, having persuaded an unsuspecting foreigner to provide the capital for starting a rival school in a neighboring street, he resigned his appointment. The rival school was a failure and Lancaster, having alienated the sympathies of the public, sank into obscurity and distress.

In 1818 he resolved to abandon his ungrateful country and begin a new life in the New World. Lancaster's System had preceded him and he was warmly welcomed from Albany to Washington. He made his first home at Philadelphia, but "rumors of debt and discreditable pecuniary transactions in England" rendered cordial relations with the Quakers impossible and he moved on to Baltimore. There he opened an "institute," but it does not appear to have been very successful and in 1825 he was glad to accept an invitation from Bolivar, the "Liberator" of South America, to organize schools for the young Republic. In less than two years he fell foul of the President and was compelled to leave Caracas.

Information respecting the remainder of his life is very fragmentary. We catch glimpses of him here and there lecturing or teaching, sometimes enjoying brief prosperity, sometimes sick and poor. In 1827 he was at New Haven, in 1828 the City of New York voted him \$500, in 1829 he went to Canada, where the Parliament made several grants to enable him to carry on his experiments in education, but in 1833, having quarreled with the Speaker, he returned to the United States. From New Haven he issued an appeal for aid pending the first payment of an annuity which the leading members of the British and Foreign School Society were subscribing to buy for their old traducer. In September, 1838, he was arranging to return to England, but an accident in a New York street ended his life on the 23d of the next month.

For about seven years after his interview with the king, Lancaster was the center of an extensive and passionate controversy. He was assailed on personal and on religious grounds. He was accused, quite unjustly, of having stolen his System from Bell (*q.v.*) and said to have invented nothing except its defects. The greatest of these was its catholicity. Lancaster and his supporters maintained that in schools attended by the children of all sects the teaching should not be distinctive of any sect. Bell's supporters maintained that the doctrines of the Established Church should be taught. The personal controversy has long ceased to interest, but the religious controversy is still unsettled in England. A hundred years ago it had one beneficial result, -- it led to the establishment of many schools in emulation or in rivalry. D. S.-N.

**LANCELOT, CLAUDE** (1615-1695) — One of the most influential teachers in the schools of Port-Royal (*q.v.*) none contributing more to the fame of the society by his pen than he. His most notable writings were unquestionably a series on learning foreign languages, the first being: *Nouvelle Méthode pour apprendre facilement la Langue latine* (1644). This was intended as an abbreviated form of Despautère, the grammar then in almost universal use, but all its rules were in French verse, whereas those in the older text had been in Latin verse. This was followed by similar texts: Greek (1655); Italian (1660); Spanish (1660).

**LANDER COLLEGE, GREENWOOD, S. C.** -- An institution for the education of girls and young women under the auspices of the South Carolina Conference of the Methodist Episcopal Church, South. The institution was founded in 1872 as the Williamston Female College and was moved to its present location in 1904 under the new title. Sub-collegiate, collegiate, and music and art courses are offered. Ten admission units are requirements. By its charter the college is authorized to grant degrees. The faculty consists of nineteen members.

**LANDSMANNSCHAFT** — The name of one type of Student Association in the German universities originating in the early part of the seventeenth century. They were originally groupings of students according to the district from which they came within each nation (See UNIVERSITIES). For a long time the residence qualification was adhered to, but later, membership was thrown open. When the *Burschenschaft* (*q v*) arose (about 1860), many of the *Landsmannschaften* were dissolved and joined the new movement. When the *Burschenschaften* were suppressed (following the revolutionary period of 1830), the name *Corps* (*q v*) was assumed by many organizations. For a time there was no distinction between *Corps* and *Landsmannschaft*, but since 1888 the latter has a separate central organization, the *Coburger Landsmannschaften-konvent* and a periodical, the *Landsmannschaften-konventzeitung*. In point of organization and exclusiveness the *Landsmannschaft* more nearly resembles the *Corps* than the *Burschenschaft*.

**LANE, ALBERT GRANNIS** (1841–1906) — School superintendent, educated in the public schools of Chicago. He was principal of the Franklin School, Chicago (1858–1869), superintendent of Cook County, Illinois (1868–1873 and 1877–1891), city superintendent of the schools of Chicago (1891–1898) and assistant superintendent (1898–1906). He was active in the National Education Association and was the author of a number of papers on educational subjects. W S M

**LANE THEOLOGICAL SEMINARY, CINCINNATI, OHIO** Established in 1829, organized under the Presbyterian church of the United States to educate young men for the ministry. All candidates must be members in full communion with some evangelical church, and for the admission to the full course should be graduates of a college or university. Diplomas are granted on completion of the full three years' course.

**LANFRANC** (c. 1005–1089) — Archbishop of Canterbury, born at Pavia. He studied law for a time, but on his father's death he went to France, and with a band of scholars opened a school at Avranches in 1039, which attracted many students. Determining to devote himself to a religious life, he went to the monastery at Bee, where he opened a school which was attended by students from France, Germany, and Italy. In 1070 Lanfranc became Archbishop of Canterbury, and in that position did much to promote learning in England by introducing and preferring foreign clerks. Lan-

franc was especially interested in the Cathedral of Canterbury, which was in the hands of monks. The *Constitutions of Lanfranc* deals with the charge and conduct of oblates and young novices, but, except for a reference to reading, no mention is made of their instruction. Lanfranc was the author of many works, the chief of these is the *De Corpore et Sanguine Domini nostri*, a defense of transubstantiation against Berengarius of Tours.

**LANGDON, SAMUEL** (1723–1797) — Eleventh president of Harvard College, from which he graduated in 1740. He taught at Portsmouth, N H (1740–1745), engaged in the work of the ministry, and was chaplain in the colonial army. He was president of Harvard College from 1774 to 1780, and the author of a number of philosophical and religious works. W S M

**LANGE, FRIEDRICH ALBERT** (1828–1875) — Philosopher, born Sept. 28, 1828, at Wald near Solingen in Westphalia, the son of a pastor who afterward became a well-known professor of theology. After attending the gymnasia of Dunsburg and Zurich, he studied classical philology at Zurich and Bonn, and taught for ten years (1852–1862) in the gymnasia of Cologne and Dunsburg and the University of Bonn. Resigning his position at Dunsburg for political reasons, he became the editor of a liberal paper and secretary of the chamber of commerce of Dunsburg, took an active interest in labor unions and various social reforms (cooperative societies, consumers' leagues, loan societies), and delivered popular lectures on philosophy. His celebrated work on the *History of Materialism* (translated by E. C. Thomas, 3 vols., 1892) first appeared in 1865 (second edition revised and enlarged, 1873–1875, later edition edited by Cohen) and was followed by two able economic treatises, *The Labor Question*, 1865, and *J. S. Mill's Views on the Social Question*, 1866. During this active period he also contributed a number of excellent articles on education to Schmid's well-known *Encyclopedia* and worked on his *Logical Studies*, which was published after his death (1877). In consequence of antagonism to his radical social and political views, Lange resigned his positions (1866) and removed to Switzerland where he devoted himself to journalism, business, politics, and teaching, until 1872, when he was called from his professorship of philosophy at Zurich to a similar chair at Marburg. Here he died, Nov. 21, 1875, in the bloom of his manhood, a victim of his strenuous devotion to work.

Lange endeavored to reconcile the prevailing scientific realism of his age with the traditional idealism by going back to Kantian critical idealism. For him materialism is a legitimate working hypothesis for the mental as well as the physical sciences, but impossible as an ultimate philosophy in view of Kant's criticism and the physiology of the sense organs, while speculative idealism belongs with religion and art to the realm of poetry, which, however, have a high value for the life of man. We cannot reach certain and objective knowledge in religion and metaphysics through reason and understanding; their value lies in their subjectivity, in their being the highest realization of the individual's spiritual self. And though natural science too is merely the product of man's mental organization, its value rests upon the elimination of self, of all teleological, emotional, religious, aesthetic, and moral presuppositions. Natural science must be supplemented by a critical idealistic philosophy, the real world by the world of values, the world of ideals.

In education Lange demanded that we keep in mind both the ethical goal and the psychological factor; pedagogy must employ the political sciences, physiology, and modern empirical psychology, and become an empirical science of national education. He criticized many of the tendencies and methods common in Germany, the mania for centralization and uniformity, the mechanization of instruction, the position of religious instruction in the curriculum, and pleaded for greater freedom and elasticity, for physical training, for training in citizenship, for realistic studies, for better training of teachers, and recommended many reforms which have since been adopted.

**LANGLEY, JOHN** (d. 1657). Headmaster of St. Paul's School, London, 1640-1657. He was born near Banbury in Oxfordshire, graduated B.A. from Magdalen Hall in 1616, and became schoolmaster at Gloucester in 1617, where he stayed till 1627. In 1643 he was one of the licensers of the press for books of philosophy, history, poetry, morality, and arts. Langley wrote *Totius Rhetoricæ Adumbratio in usum Paulinæ Scholæ* (1644) and an *Introduction to Grammar*. Dr. Edward Reynolds, afterwards Bishop of Norwich, who preached Langley's funeral sermon, 1657, spoke of

Langley as "a learned man, a historian, cosmographer, and a great antiquary in the most memorable things of this Nation." He thus entered into the tradition of the great antiquary-schoolmaster, William Camden (*q.v.*), and marks the growing tendency toward widening the field of interest of schoolmasters beyond the merely classical to the recognition of the claims of England, in its language, history, and literature, to the attention of masters and pupils of English schools. **LANGUAGE, ENGLISH** — The English language as a clearly differentiated branch of scientific and academic study was not fully recognized until the development of the modern science of philology. In the seventeenth century interest in the antiquities of the English people had led to a certain amount of examination of the language of the older periods, mainly with a view to the translation of Anglo-Saxon texts and then use in ecclesiastical history and polemics (see **ANGLO-SAXON**). Although these earliest investigations were not carried on in a thorough or systematic way, a number of works were then written, e.g. grammars and dictionaries (*q.v.*), which were of some use to later students of the language. In the succeeding century students of language were interested in the subject mainly from a philosophical point of view, and attempts were made, always upon an insufficient basis of fact and observation, to explain language as a universal human activity according to the rules of a systematic logic. Attention being directed mainly to theory, the study of the facts of the speech languished. Of the English philosophical linguists one of the most ingenious was Lord Monboddo, James Burnett, who published his *Origin and Progress of Language* in six volumes, from 1773 to 1792. More representative of linguistic scholarship specifically, and perhaps the most important work of the eighteenth century dealing with the English language, is J. Horne Tooke's *Epæ Proœnta, or the Diversions of Purley*, the first volume of which appeared in 1786. This work, which is concerned mainly with etymology, was undertaken in a casual way as result of a lawsuit in which Tooke was concerned, the decision of which turned upon the meaning of certain English prepositions. Although the book is full of the wildest theoretical derivations of words and of unfounded linguistic generalizations, it nevertheless shows considerable information and even scholarship of

a miscellaneous and unsystematic kind. It serves as a fair index to the state of knowledge with respect to language in its time, and shows also that the lack of a proper method was the main reason why much of the linguistic investigation of the philosophical students of language has proved unsound and valueless.

The historical and scientific study of language according to modern methods begins with the foundation of the science of philology in the early nineteenth century. The scholarly point of view with respect to the study of the individual languages, *e.g.* English, French, German, etc., has in general followed the changes in the theoretical conception of the whole subject of philology (*qv*). Two important and differing conceptions of philology may here be noticed. The first and earlier of the two is that which was formulated by Friedrich August Wolf (*qv*) in his various writings on classical antiquity, especially the literature and art of Greece. It was left to his followers, Boeckh, H. Paul, and others, to extend his conception of philology to other civilizations, especially to the Teutonic civilization of Europe. The greatest achievement of the Wolfian conception of philology has been the production of the *Grundriss der germanischen Philologie* (2d ed., Vol. I, 1896), under the general direction of H. Paul, but with the collaboration of various scholars in special fields. The inherent difficulties of the synthetic Wolfian conception of philology, and the natural tendency of all such studies toward greater differentiation and specialization, prepared the way for the second and more analytic conception of philology, which is the one prevailing to-day, at least in practice, and the one which has been most fruitful of results. This theory of philology makes the subject in many respects coincidental with the science of linguistics, the tendency in this direction being apparent even in Paul's *Grundriss* from the greater relative importance of the fifth, the linguistic section, as compared with the other sections of the book. The founder of the modern science of philology or linguistics, as distinguished from Wolf's imaginative and poetical conception of the subject, is usually assumed to be Franz Bopp (*qv*), born 1791, who chose as his particular subject of investigation the origin of the inflectional system of the Indo-Germanic languages. Bopp's method was comparative, and in the course of his investigations he not only arrived at a theory of his own with respect to the origin of inflection, but a more important result of his work was the detailed proof of the common relationship and origin of the Indo-Germanic languages, a fact which had been guessed before Bopp's time, but never credibly demonstrated. The conclusions of Bopp established the comparative method of linguistic investigation upon a sound basis, and this method has more or less colored all subsequent study of language. Still further

differentiation was brought about by Jacob Grimm (*qv*), who published in the year 1819 the first volume of his *Deutsche Grammatik*. To Grimm belongs the credit of first clearly formulating the methods and the laws of the historical study of language. His procedure, familiar to every novice to-day, was to place the various forms of a special language, English for example, in a chronological sequence from Anglo-Saxon to Modern English, the conclusions drawn being those which arose immediately from the observation of the facts thus arranged. Grimm declared himself hostile to all general abstract and logical ideas in the study of language, thus placing himself squarely in opposition to the philosophical and logical school of linguists, which still flourished in his day. Grimm also regarded language as a purely social product, subject to the laws of natural growth, like all other human institutions, and although this aspect of language was not extensively developed by him, he deserved credit for being one of the first to perceive it clearly. Grimm likewise deserved recognition for being the first student of language to see clearly the importance of the sounds of language, historically considered, and also of the forms of a language other than the standard language, that is, of the popular dialects, for the understanding of the history of the language. One other distinction Grimm also may claim, that of being one of the earliest scholarly editors of Teutonic texts, Anglo-Saxon as well as German. Grimm, with his many-sided activity, may stand, therefore, as a type of the best among historical philologists, and the value of his methods may be inferred from the fact that the results of his investigations are to a large extent accepted to this day.

The aim of the historical student of language is theoretically less ambitious than that of either the Wolfian philologist or the comparative student of language, but as his field of observation becomes more restricted in extent, it is covered in a correspondingly more detailed and exact way. The final purpose of the historical students of the English language has been so to search and elucidate the material of the language as to enable them to present a complete picture of it. To this end the student must devote himself to the minute study of all the objective facts of the language, in phonetics, in morphology, in vocabulary, and in syntax. Before such a vast array of facts can be presented in a systematic way for any single language, a great deal of counting, cataloguing, and classifying is necessary, investigation of a more or less mechanical and statistical type, which the modern student, at least of English, thanks to the earlier investigators, to a considerable extent escapes, but which is still sometimes unjustly made the reproach of linguistic specialization by those who are hostile to it, it should not be forgotten, how-

ever, that the present simplicity and system in the history of the language are largely the result of statistical labors, laws in language being nothing more than observation of individual instances. Having thus gathered and classified the facts of his language, the historical student, by placing them in chronological sequence, shows that later usages arise regularly out of earlier, such observations constituting a rule or law of the development of the language. In general the earlier historical students of language concerned themselves but little with the causes or the psychological or physical explanations of the laws which they recorded. They looked upon it as their task to state empirical laws, trusting that when a sufficiently large area of observation had been thus covered, many questions that appeared difficult of solution would be answered of themselves. In this hope they were not disappointed, but obviously a mere descriptive statement of the facts of a language is not all that can be expected of the historical student, and it is now assumed that the descriptive laws are preliminary to the explanation of the meaning of the facts as illustrating general social and psychological processes in language. This fuller realization of the significance of psychological activities and of social custom in language is due to the investigations of Paul, Stenhal, and in general of the contemporary school of linguists, the study of the physical side of language by the flourishing modern school of phoneticians has been productive of particularly valuable results.

These are, in general, the principles upon which the modern scientific study of language is based, but a brief summary of the more important results of the historical and descriptive study of the English language will best show what has been accomplished and what remains to be done in that particular field. In the first place the duty of the student of language concerning which there would probably be least difference of opinion, that of transferring the early literary monuments of the language from perishable and inaccessible manuscripts to multiplied printed copies, assuring their preservation and general accessibility, has been performed. The important manuscripts have been transcribed and printed, most of them having been published in the volumes of the Early English Text Society. Some of the manuscripts have been photographed, but this method of producing exact mechanical copies of the originals has not as yet been extensively employed, although the time is doubtless not far distant when at least valuable manuscripts will thus be brought within the reach of all libraries. Unless unexpected and startling discoveries are made, there is consequently nothing to be added to the published documents that will, in any material way, alter the conclusions concerning the English language which may be drawn

from those now available. This does **not** mean, however, that the editing of English texts is a closed account. The Early English Text Society publishes lists of unedited manuscripts which should be copied and printed, and new editions, taking account of the results of more recent investigations, of much of the literature of the Old and Middle English periods are greatly to be desired. There is at present no edition of the *Beowulf*, the most important monument before the Conquest, in English or in German, which gives an adequate and comprehensive treatment of the poem. The text has been frequently printed, accompanied by glossaries and textual comment, but there is no modern summing up of the poem in all its aspects as an historical and literary record. With a few notable exceptions, the same is true of the main monuments of Anglo-Saxon literature, verse and prose, and in the preparation of exhaustive editions of the texts now available the English scholar has an important and pressing service to perform. Middle English texts have been, on the whole, more thoroughly edited than Anglo-Saxon, and of recent years some attention has been given to the careful editing, from a linguistic as well as literary point of view, of texts of the Early Modern English period, especially of dramatic texts.

In the study of the sounds, the inflections, the vocabulary, and the syntax of the language, much has also been accomplished. The treatises of Ellis, Sweet, Jespersen, Sievers, and others present a fairly comprehensive history of English sounds. The questions which await solution are more or less minor ones of the limits of dialects, of the values of occasional manuscript symbols, of the individual characteristics of certain writers, etc., besides, of course, many theoretical questions of the origins, the causes, and the processes of sound changes. The study of English inflections has been carried much nearer completion than that of English sounds. The progressive changes in the system of English inflections, from Old to Modern English, their chronological divisions and dialectal variations, are subjects of elementary knowledge to the student of the language, and may be easily observed in the many schematic statements in the various manuals and histories of the language. On the other hand, the growth and development of the vocabulary, from the complex nature of the subject, is less readily presented in historical survey. The outlines of the subject may be followed in the various publications of Professor W. W. Skeat, who has made this field particularly his own; and the material for a comprehensive history of the English vocabulary is being gradually presented in the volumes of the *New English Dictionary*. The syntax of the language, on the other hand, although it has been by no means a neglected field, still presents its main problems unsolved, and, in

Main Entrance and Façade

Bird's-eye View from Foothills to the River

An Inner Court

Memorial Church

LELAND STANFORD JR. UNIVERSITY

fact, unstated. The results of syntactical investigations in English seem to be out of proportion to the amount of time and application which have been spent on them, and certainly are not equal in importance and generalizing value in their own field to the results of linguistic investigations in other directions, for example, in phonetics or morphology. The reason for this is probably to be found partly in the inherent difficulty of the subject and partly in the lack of an intelligible and generally accepted method. Syntax may be defined as the study of language as it takes form in the expression of thought, that is, of the formation and combination of sentences. It includes thus not only the use of the various cases, tenses, moods, genders, etc., according to the laws of concord, but also all departures from grammatical norms, word order, phrasing and the grouping of complex ideas, perhaps also the use of tones and inflections of the voice, of gesture and facial expression in coloring and assisting the meaning of the phrase. A complete syntax of the language would naturally include not only the written literary language, but also the colloquial spoken language of everyday intercourse, as the dictionary does, for example, in the treatment of words. Such a syntax of the language as is here described may possibly never be written, since the difficulty of reducing the multitudinous facts of observation to systematic statement seems humanly almost insurmountable. Consequently no attempt has ever been made to write a descriptive, historical syntax of the language, parallel to the descriptive statements of inflections, sounds, and vocabulary. In general it would seem that in the study of syntax the historical method must take a secondary place, and must serve as a guide and corrective to the student, rather than as an end in itself. It is possible that by studying all the recorded forms of a past period, for example, the Old English period, an approximately complete norm of Old English syntax could be realized, and by placing beside this norm a transition English, a Middle English, and a Modern English syntax, to mention only the larger chronological divisions, conclusions of far-reaching significance would undoubtedly result. But a complete normal syntax for any one period is still far from realizable, much less a series of syntactical pictures for a group of successive periods. More practicable than such an endeavor to build up a general descriptive and historical syntax of the English language is the attempt to show how and why different specific syntactical forms arose. The historical study of the phenomena thus takes its place as an aid in the psychological explanation of them. Instead of placing before himself the hopeless task of comprehending the whole vast structure of the language, the syntactical student may more profitably limit himself to following out the psychological

principles underlying certain forms or groups of forms that have their principle of unity within themselves. He may thus disregard and free himself of the burden of the obvious and the indifferent, and give his attention to those phenomena which will enable him to gain some insight into the spiritual life which serves as a background for the language, and which carry with themselves results which may be intelligently estimated and valued.

The work which, better than any other, may serve as an index to and a summary statement of the results of the modern scientific and historical study of the English language is the *New English Dictionary*. This work originated from a suggestion of Archbishop Trench, who in the year 1857 proposed the collection of materials for a new dictionary which should be a worthy record of the English language. This collection of references was immediately begun, quotations being taken "from all the great English writers of all ages, and from all the writers on special topics whose works might illustrate the history of words employed in special senses, from all writers whatever before the sixteenth century, and from as many as possible of the more important writers of later times" (Preface to Vol. I, p. 5). The dictionary is, therefore, not a compilation from older dictionaries, but all the material used in it was collected for this specific purpose. "The aim of the Dictionary is to furnish an adequate account of the meaning, origin, and history of English words now in general use, or known to have been in use at any time during the last seven hundred years. It endeavors (1) to show, with regard to each individual word, when, how, in what shape, and with what signification it became English, what development of form and meaning it has since received; which of its uses have, in the course of time, become obsolete, and which still survive, what new uses have since arisen, by what process, and when, (2) to illustrate these facts by a series of quotations ranging from the first known occurrence of the word to the latest, or down to the present day, the word being thus made to exhibit its own history and meaning; and (3) to treat the etymology of each word strictly on the basis of historical fact, and in accordance with the methods and results of modern philosophical science" (Vol. I, p. 6). The first volume of this work, published by the Clarendon Press, Oxford, appeared in 1888, and the whole is now nearing completion, the latest section (1911) coming down to "Tezkere". In its combination of thoroughness with exactness, the *New English Dictionary* represents the highest achievement of modern English scholarship. It is sometimes called the *Oxford Dictionary*, from the place of its publication, or *Murray's Dictionary*, from the name of its general editor.

In the academic development of the subject, the scientific study of the English vernacular

made its way much less rapidly in England than in Germany. In the latter country the study of the modern Teutonic languages, English among others, had already been extensively developed by such scholars as Bopp, Grimm, Schleicher, and others, before it received recognition in England in the appointment of Max Müller to the chair of comparative philology in the University of Oxford, in 1868. The explanation of the fact that German scholars have devoted so much time to the historical study of English is obviously to be found in the practically equal significance of the earlier periods of English for the history of English and German. The main stress in these earlier studies was therefore placed upon the comparative aspects of linguistic history. Only slowly and with difficulty did the study of the English language specifically detach itself from the larger subject of comparative philology. Aside from the Rawlinsonian Professorship of Anglo-Saxon (see *ANGLO-SAXON*), no official provision was made in the University of Oxford for the study of the English language until the establishment of the Merton Professorship of English Language and Literature in 1885. Only within the last twenty-five years, consequently, has the study of the English language received final recognition as a distinct and important part of the curriculum of an English university.

In America specific provision for the study of the English language by the creation of professorships in English philology or English language has also been made only in recent years. Among earlier linguists, for example, William Dwight Whitney was first Professor of Sanskrit in Yale University, after 1870 Professor of Comparative Philology, Francis James Child was Boylston Professor of Rhetoric and Oratory in Harvard University from 1851 to 1876, and after the latter date Professor of English. A pioneer student and teacher of the English language in America is Francis A. March (*qv*), since 1856 Professor of English Language and Comparative Philology in Lafayette College. Within the past generation the study of the English language has grown rapidly in Continental, English, and American universities. Whether or not special provision is made for such work by the appointment of a professor of the English language, courses are now given in all universities which cover the various aspects of the history of the language, at least in the earlier periods of Anglo-Saxon and Middle English. The modern period, for obvious reasons, is much less generally studied than the earlier periods. The historical study of the language remains, however, largely a university subject. Apart from their purely scholarly and scientific significance, university courses in the English language are usually regarded as a part of the preparation of prospective teachers of English in secondary schools or colleges. But in recent

years a number of non-technical manuals of the history of the English language have been written, not from the point of view of rhetorical usage, but from a more purely linguistic position, and with the help of these books the historical study of the vernacular has made considerable progress in the colleges. It is generally assumed that the attitude of students toward their native speech in the secondary and in the lower schools should be practically constructive and not scientific or analytic, and consequently the historical study of the English language has not been introduced to any considerable extent in such schools. The work of the lower grades in grammar and composition (*qv*) is usually placed pedagogically under the head of language, but such "language work" obviously cannot attempt anything systematic or scientific.

The question of the content and the value of the historical study of the English language as part of a liberal education for English-speaking students is one that is frequently discussed and may be most conveniently considered from two points of view, first as to its practical usefulness, and secondly and more disinterestedly, as a subject of knowledge and reasonable curiosity that deserves to be cultivated for itself alone. The practical advantages to be derived from the historical and scientific study of the vernacular are mainly such as arise from the acquisition of a clearer understanding of the nature and the uses of language as a medium of communication, thus enabling the student to become more certain and confident in establishing the principles of his own use of language. The study of the changes which have taken place historically in the language, for example, is likely to beget in the student a more intelligent and less dogmatic attitude toward practical questions of the contemporary speech than is frequently found. He may thus be brought to realize that language at all times has been a social possession, flexible and made up of compromises, and that its forms have always been determined, not by external authority of any kind but immediately by the practical uses to which the language was to be put. In this way the fact of the speaker's or writer's own first-hand constructive power over language is brought home to him. Such a realization is at present particularly necessary and helpful for the American student, whose sense of reverence for the authority of the standard and classic language of literature has been developed at the expense of his own individual feeling for expressiveness by dogmatic instruction in rhetoric and composition. Since the historical study of the language acts usually not as a sedative but as an excitant upon the student, obviously the place for it is not in the early but in the later years of the college course. It would seem best to conduct such study in the college not in a detailed, sys-

tematic way as the science of language, but less technically by calling attention to particularly suggestive and illuminating examples of the way in which language reveals the activities of the mental life which lies back of it. Perhaps the most simple and effective avenue of approach to the study of language for the non-professional student is through etymology and the study of vocabulary in general. The study of phonetics is rendered unusually difficult for younger students because of their inability to objectify and observe their own speech sounds as distinguished from the arbitrary and inconsistent symbols of the English language, but the subject is one that cannot very well be neglected, and students should be trained at least to observe contemporary use and to understand the meaning of phonetics as applied to the explanation of etymological forms. It is perhaps easy for university-trained instructors to make the mistake of attempting too much in elementary linguistic courses, often doubtless from a feeling of the dignity and importance of the science of philology. But with all due reverence for the science of philology, one should realize that the college is hardly the place for scientific linguistics, and that the purpose of the instruction should be to extend the area of the student's interests and to shape his powers of linguistic observation rather than to present an organized science of the language. The discussions of contemporary, especially of divided, uses are particularly instructive, and the students may thus be led to form the habit of analyzing and passing judgment for himself on the linguistic facts which he observes.

A certain amount of the study of language is obviously necessary to the reading and appreciation of whole periods of English literature. The main question for decision here is, just how much training in language is necessary before a student may be said to be able to read Shakespeare or Chaucer or the literature of the periods before the Conquest. Opinions will doubtless vary, but it seems certainly a safe rule that the student should give as much attention to language as is necessary to enable him to understand the meaning of his author exactly. If early texts require what seems an excessive amount of preliminary linguistic preparation, they might better be omitted altogether than read carelessly and inaccurately. The student who does not understand the syntax or the special meanings of words in Shakespeare, who misses three or four out of every ten words in Chaucer, and is never sure of his grammar, may blunder through the texts and come out at the end with some sense of enjoyment, and of exhilaration, even though confused, imagination; but he can never have any feeling of assurance that he has read his author aright. English literature as early as Shakespeare or earlier should not be read with the same attitude of mind toward its language as is maintained

in reading Pope or Scott or Tennyson. If one wishes to treat with justice the language in which the earlier literature is written, one must assume a questioning attitude toward it, just as one does toward the social and literary traditions which the earlier literature records. In reading the literature of the Old English period the necessity of studying the language is so obvious that it cannot be avoided. It is chiefly in the intermediate period between Old and Modern English, when it is so easy for the careless reader to delude himself into the belief that he can get at the soul of an author without knowing how to define his words or to parse his grammar, that the understanding of literature is likely to suffer from the neglect of the study of language. The only safe rule is to examine every linguistic usage which differs from normal contemporary usage, and, if the burden of such examination is too great in any texts, to defer the reading of such texts until the student is ready to undertake them.

From the second point of view, the amount and the nature of the information with respect to the language which the well-informed student may reasonably be expected to have may be briefly summarized. The grouping of languages into families, which is one of the most important results of the comparative method of linguistic study, presents new and illuminating ideas to the student, and consequently English should be placed among its related languages and some consideration should be given to the general question of the origin and differentiation of dialects. Within the field of English specifically, the three great chronological divisions of Old, Middle, and Modern English should be distinguished, and the peculiar characteristics of each period, especially in sounds and inflections, may be profitably examined in detail. In connection with the study of sounds historically, it is extremely important that the student of the vernacular should receive training in the observation and analysis of contemporary sounds and vocal processes, both in his own speech and in that of others. It is only by persistent practice that the student can become truthfully and exactly observant of the actual phonetic character of speech, that he can, for example, distinguish the audible forms of English words, which are the vital and changing forms, from the visual forms, which in English are usually arbitrary and conventional. In the study of speech sounds, it is advisable, if not absolutely necessary, to make use of some approximately scientific method of sound notation, the most practical being a simple phonetic alphabet in which the symbols differ as little as possible from the standard alphabet, but in which no symbol has more than one value. Such an alphabet is employed in the indications of pronunciations in the *New English Dictionary*. The use of a phonetic alphabet will lead naturally to the consideration of the history of standard English orthog-

raphy and of the principles which should govern the users of the language in their attitude toward spelling. The study of the English vocabulary may be approached from many different points of view; but so far as the history of the language is concerned, attention should be directed at least toward the various elements of which the vocabulary is composed, the sources whence these elements are derived, and the occasion and method of the introduction of borrowed words into the language. It is important that the student should understand the principles upon which the science of etymology is based as a corrective of the popular superficial method of etymologizing. The stylistic value and color of the elements of the vocabulary are matters mainly of rhetoric, but the study of the history of words leads over insensibly and unavoidably to a consideration of their values in use. Finally, the events in the history of the English people which have been important for the development of their language, for example, the Roman mission, the Danish invasions, the Norman Conquest, etc., will indicate the relation which exists between the life of the people and the growth of their language. In general the aim of an introductory course in the history of the English language should be to prepare the student, first, to use intelligently the material contained in the various handbooks, dictionaries, grammars, and other storehouses of information with respect to the language, and secondly, to observe with some degree of accuracy the facts of his own speech and of the speech of his environment. An intelligent understanding of the fluctuating material of the native speech cannot be obtained otherwise than by some such attention to the elementary facts of its history and use.

**LANGUAGE, PSYCHOLOGY OF.**—Any form of expression by means of which one individual conveys his own emotional or ideational states to some other individual may properly be called language. Thus the cries of the wild animal are very properly referred to under the term "animal language." Gestures have long been recognized as forms of language. The highly developed forms of oral speech and written communication which are characteristic of human beings are merely the final stages of a long evolutionary series of forms of social expression. The earlier writers upon language, not recognizing the relation between the highly developed forms of language and the more primitive forms of expression, devised various theories of the origin of language which assumed a sudden rise of this mode of expression. Thus, it was regarded as a special gift of God to man, as a mark of his superiority to all other animal forms.

Again, it was held that man through his power of imitation of natural sounds suddenly hit upon the device of using these sounds as a means of representing the external objects imitated. The cries of various animals, for example, were supposed to have been repeated whenever man wished to communicate with his fellows that the animal imitated was near at hand. These theories have been superseded in all later discussions by a more comprehensive account of the whole evolutionary series of forms of expression to which human language belongs.

The great work of Wilhelm Wundt, *Völkerpsychologie*, brought out the psychological importance of the study of language. In the first two volumes of this work, Wundt calls attention to the fact that language is nothing more or less than a highly evolved form of emotional expression. In the earliest stages of emotional expression the movements of the vocal cords are not to be distinguished from various other forms of emotional activity. Thus, the infant in distress makes noises exactly as he kicks with his legs and threshes about with his arms and hands. The facial contortions of the infant, including the movements of the organs of the mouth, are purely spontaneous and individualistic modes of behavior. All of these different types of behavior are familiar to the student of the emotions (*q v*).

The first stage of the evolution of language may therefore be described as the strictly individualistic and the emotional stage. A differentiation begins to appear among emotional expressions as soon as the individual becomes a member of the social group. Certain

of the emotional activities of such an individual are of special importance because they induce imitation in his fellows. Thus the facial expressions are of much greater social importance than the internal changes in the circulatory system. A person who is angry experiences a change in the rate of his heart beat, and at the same time shows a fixed contraction of the muscles of his hand and jaw. The expression of the face produces in those who are about the angry person either imitation or a definite protective reaction, while the inner change which takes place in the angry person's circulatory system passes wholly unobserved. This social significance of the observed reaction tends to raise it to the higher level. In the first place it is brought more or less under control by the individual himself, and in the second place it calls for a reply from other members of the social group. It becomes thus a medium for the transmission from individual to individual of emotional states.

The first types of communication are those which transmit purely emotional states. The frightened animal may induce a stampede in the other animals about him through mere social imitation. He cannot at this stage of development indicate in any way the ideas which are in his own mind. He may, however, communicate the emotional state of fear in all completeness. The second stage of language is, therefore, to be described as the stage of emotional imitation. It is at this stage that most animals come to a standstill in the evolution of language. The frightened animal may indicate by its cry or action its internal emotional state, but it never produces a terminology which makes it possible to tell about the objects which it sees.

In human society, and possibly among the higher animals, there develops through expression the ability to communicate ideas as well as emotions. These ideas are at first very simple in character. Thus the hungry animal may go through the movements of taking food. Certainly among primitive human beings this mode of communication through pantomime is very common. The gestures that are involved in such communication through pantomime have been called natural signs. They are natural in the sense that they are partial activities of the type which the individual would perform if he were in the actual presence of the object which he wishes to depict. They are signs in the sense that they do not deal with the actual object, but merely recall the object to the two parties to the communication. Almost any simple human activity can be communicated in this way. Thus, the act of digging or throwing, the act of running or of looking toward some object in the distance, can be made to convey to another human being a very large fund of experience. Attention should be drawn to the fact that even the higher animals do not succeed in carrying this type of com-

munication to any high stage. Indeed, it may be doubted whether they succeed at all except by the mere accidents of emotional expression such as was described in the last paragraph. At all events, such simple gestures as those of pointing are never developed in any conscious way among the animals, whereas, they appear in all races of men. Natural signs, or primitive pantomimic gestures, may be distinguished from forms of emotional imitation as a third stage of language development.

There are certain disadvantages in the use of the hands for social expression. These disadvantages must have made themselves very early felt in primitive society. The use of gestures would interfere with any form of manual occupation. The use of the hands for expression would also be disadvantageous in any parley between enemies, for it would involve going out into the open, and also it would limit the ability to use weapons on the part of the person who was making an effort to communicate with others.

Finally, there is a fundamental fact of development which must have operated to limit the use of the hands for purposes of purely social expression. This fundamental fact appears in a natural tendency of the hand to develop a whole series of habits of movement which are not social in their character at all. The hand evolved in the direction of the manipulation of objects, and in so far as the various arts were cultivated, the hand must have been devoted more and more to forms of skill, and less and less to the incidental forms of emotional expression which are natural in earlier stages of development. This can be seen in the life of the infant. The hands gradually come to be specialized organs for seizing objects and holding them, and just in so far as the hands and arms are trained in the direction of manipulation of physical objects, they are less and less used for purposes of expression. The vocal cords, on the other hand, have no value as organs for the manipulation of external objects. They are very naturally utilized, therefore, as organs of emotional and social expression. They are sufficiently delicate in their musculature to make possible a great variety of acts, and they are under the control of the speaker to such an extent that they become admirable avenues for social expression. No physical medium is needed for oral expression except the air, which is always present, thus the vocal cords are superior to gestures for communication in the dark, and for parley between enemies and friends who are hidden from each other by intervening objects.

Such considerations as these indicate some of the reasons why in later human evolution the vocal expressions are selected from among the observable forms of behavior for the higher uses of human language. Oral expression is, however, not the exclusive means of these higher forms of expression, and we find now

only the vocal apparatus, but also, though to a less extent, the hands, serving the purpose of the fourth stage of language development, to the description of which we may now turn.

The fourth stage of language development differs from the period of natural signs in that the signs which are employed at the higher level have less and less immediate connection with the situations to which they refer. The sign needs now only to symbolize in some manner the situation to which it relates. Thus we find in mature language that there is no traceable connection between many of the sounds which we employ and the objects to which they refer. Indeed, it is doubtful whether such a connection could be traced, even if we had the complete history of the word. One interesting illustration of the purely arbitrary character of language expression is found in the word "gas." This word was invented by the Belgian chemist, Van Helmont. He needed a word to express the state of matter which is denoted by this term, and so employed the term without any historical antecedents. In this example we have an admirable illustration of what is meant by the symbolical character of an expression. The vocal expression is connected in human experience with a certain idea. Once the connection between the sound and the idea has been made, the sound will in all future experiences tend to arouse the idea. There need be no natural connection between expression and idea, provided the connection has been established in some way, and has been commonly accepted. We may describe this stage of language development by saying that associational connections have been substituted for natural connections. Associational connections are frequently established between gestures and ideas as well as between sounds and ideas. Thus the deaf and dumb of our own generation have a symbol for the word "make" and all of its derivatives. This gesture consists in the crossing at the wrists of the two folded fists. It is enough for the purpose of human experience that there should be a connection between this gesture and the ideas. The gesture carries the ideas to any one who is trained in the interpretation of this symbol. It is obvious that associational language requires a high form of mental development, the individual must have a stock of ideas which can be related to the various forms of expression, and he must, in addition, have sufficient mental power to make it possible for him to hold the connection between the mode of expression and the idea.

For purposes of education, it is this final stage of language expression that is of importance. The child in the school finds it necessary to learn a vast body of ideas and the words which go with those ideas. Earlier stages of emotional expression are not of any very great importance in education, although the control of the facial expressions is undoubtedly one of the lessons that must be learned in all social groups.

After the associational stage of language has been reached, further processes of evolution go forward in the changes that take place in the meaning and character of words. Thus, there is a continual development of meanings. This is often illustrated in the English language, as is shown in Trench's *English Past and Present*. The word "villain," for example, which originally meant a laborer about a country place or villa, has gradually modified its meaning until it has the present well-known significance. Furthermore, the sounds of words undergo a change. The history of English shows very plainly, by the different rhymes which are employed at different stages of the development of the language, that there is a tendency for many sounds to grow shorter in their articulation. Qualitative changes also appear as languages evolve. The transition from German to English, or between any two languages, is accompanied by a very notable modification in the quality as well as in the length of the sounds involved. Thus, the German word *Tag* is the same in its origin as the English word *Day*.

More significant than these gradual changes in language is the fact that individual interpretations of words may differ to such an extent that the same sound may be related in two different experiences to wholly different meanings. The ambiguity of words has often been commented upon. Locke, in his *Essay on the Human Understanding*, discusses at great length the dangers that grow out of the ambiguous use of words, and this has been the subject of frequent comment on the part of educators since that time.

With the development of written symbols the means of human communication has been very greatly enlarged. Written symbols appeared much later than oral conventions. In the earliest stages of writing, there was the same tendency to use natural signs that we find in gesture language. The earliest written symbols were diagrammatic sketches of the objects which the writer would call to the mind of the reader. The diagrammatic sketch came to be very much simplified as the power of interpretation increased. Finally, in the occidental world, some Semitic nation, probably the Phoenicians, discovered the possibility of relating directly the written symbols to the sound elements of language. That there is no necessary intellectual connection between the elementary sounds and separate letters is well attested by the Chinese language, where the written symbol is related to the whole word rather than to the single sound. After the association of the written symbol with the single sound had been established, various changes appeared through the gradual modification of the sound connected with the letter, and through various modifications in the form of the letter itself. (See WRITING.)

Language instruction has always occupied

a very important place in the schools. Since it is a highly evolved mode of expression it requires laborious cultivation on the part of the child. Indeed, the school may be described as very largely an institution which introduces the child to this conventional mode of expression, and gives him the necessary meanings with which to interpret language. Reading and writing have, therefore, constituted a very large part of the elementary course of study. From time to time reformers have vigorously advocated a reduction of the amount of energy devoted in the school to the instruction in language, on the other hand, the tendency has often been to enlarge the emphasis upon language by the introduction of foreign languages as well as vernacular. **LANGUAGES, ARTIFICIAL** — The endeavor to fashion an artificial language has a long history, and has assumed many different forms. An imperfect kind of language which appeals only to the eye has been in practical use for half a century and more in the code of signals employed in naval and military communication. Still older are the attempts to construct a universal artificial language which could be both written or printed and spoken. Descartes in 1629 outlined a scheme for a universal, philosophical language. His plan was to establish a system "of all the thoughts which can enter into the human spirit," taking first the simple ideas, and combining these simple ideas in order to form the more complex ideas. Each simple idea was to have its appropriate character or symbol, like the primary numbers of the arithmetical system, and complex and more limited ideas were to be expressed by combinations of these characters in such a way that the elements of a word would

express mathematically its logical content. "The invention of this language," says Descartes, "is dependent upon a true philosophy, for it is impossible otherwise to indicate all the thoughts of the human mind, or to put them in order, or even to distinguish them in such a way that they shall be clear and simple. If the primary ideas which are in the human imagination and of which all things that men think are composed, were thus set forth and generally accepted, I would venture to hope for a universal language easy to learn, to pronounce, and to write, and, most important of all, one which should and the judgment, presenting to it so distinctly all things that it would be almost impossible for it to deceive itself. With the aid of such a language, a rude rustic could better judge of the truth of things than the philosopher can now do."

This theory of Descartes is at the base of a great many attempts to construct a universal philosophical language. It supposes first a systematic program of all logical ideas, classified under general heads with sub-classifications leading to the particular and concrete, and second a set of symbols, numerical or literal, chosen arbitrarily to designate these ideas. The result would be a kind of algebra of language, the meaning of every combination of symbols being absolutely fixed by its place in the philosophical system. Descartes himself never worked out his theory into a practical form, but this was done by others. George Dalgarno, a Scotchman, published in 1661 his *Art Signorum*, a universal and philosophical language, followed in 1668 by Bishop Wilkins' *Essay towards a Real Character and a Philosophical Language*, in which the vocabulary is based upon forty logical categories, supposed to be exhaustive of all general and primary ideas. Leibnitz (*q.v.*) carried further the methods of Dalgarno and Wilkins, against whom he directed the reproach that they were not sufficiently philosophical. Leibnitz drew a close parallel between mathematical and logical processes. Every thought having, as he maintained, as fixed a character as a number, the primary ideas may be designated by primary numbers, and all complex ideas merely as combinations of primary ideas. The combinations of ideas are thus supposed to be analogous to multiplication in arithmetic. They may be expressed by numbers, and the problem of a universal language consists simply in transforming the mathematical formulas into words that may be pronounced. In carrying out this seemingly simple plan, Leibnitz, in common with all the other inventors of philosophical languages, makes use of a system extraordinarily complicated when one looks at it from the point of view of the practical user of language. But it is apparent that the advocates of an artificial philosophical language have paid little heed to questions of practical use. They have been

concerned primarily with the attempt to systematize and then to symbolize all logical ideas, and the discredit which has in general fallen upon the program methods of systematic logic has deprived their efforts of both scientific and practical interest to the modern student of language.

An entirely different point of view is usually assumed by modern theorists in the construction of artificial languages. Instead of a universal philosophical language, they generally advocate an auxiliary international language. The purpose of such a language they assume to be to supplement the mother tongues of the various countries in order to make international scientific and commercial communication easier by the use of one arbitrarily selected language in the place of the present variety of local and national speeches. They assume further that no national idiom, either a dead language like Latin, or a living language like English or French, has any chance of being accepted by a sufficient number of the nations concerned to answer the purposes of an international speech. It is not supposed, except by extreme theorists, that a single artificial language of this practical character will ever supplant native idioms in the familiar intercourse of daily life. The principal aim of these advocates of artificial languages is not "the federation of man" through the imposition of one speech upon all peoples, but the strictly utilitarian end of greater ease of intercommunication. It is apparent that such a language in any case must appeal to a relatively limited number of people, mainly to travelers and to those interested in international science and commerce. It is also apparent that the need of an international auxiliary language is greater in Europe than it is in America, and that the people of relatively small countries like Denmark, or of countries which use a language difficult to learn and not generally known, like Russian and Hungarian, will profit more by an auxiliary language than will the people of Germany, France, or England. But the great advantage of such a language to all nations cannot be denied, and the main difficulty to be met is not a theoretical one, but the practical difficulty of getting one language generally accepted.

The first important experiment of recent years in the manufacture of an artificial language was that of Schleyer, who called his language Volapuk. A Roman Catholic priest, Schleyer perhaps felt in an especial way the need of an international medium of communication. The year 1879 is given as the date of Schleyer's discovery, or invention, of this language, of which he wrote a grammar that has passed through a number of editions. The language employs the Roman alphabet, and bases its vocabulary mainly upon English, because English is the language of the largest number of people who might be supposed to be interested in an artificial language. But inas-

much as the sounds of Volapuk are not the sounds of the English letters, even an English-speaking person would find it difficult to understand the spoken form of a word in Volapuk. As to the grammatical system, Schleyer invents more or less arbitrary inflectional elements to indicate case and tense relations, the parts of speech, etc. He also accepts other arbitrary rules, for example, he excludes the sound and the letter *h* altogether, and to a large extent the letter *r*, since the Chinese find this latter sound difficult to pronounce. Since no word, according to his rules, can end in a spirant, the English-Romance word *rose* becomes *lol* in Volapuk. To avoid the final spirant, the English *sooth* becomes *tut*, English *program* becomes *ploqam*. And since every root must end in a single consonant, English *friend* becomes *flen*. As far as possible, roots must also be monosyllabic, and Schleyer therefore removes initial and final unstressed syllables, with the result that *compliment* becomes *plun*, French *remarquable* becomes *makab*. These few illustrations will indicate the main defect of Volapuk. Although it purports to be based mainly upon the most familiar of European languages, English, French, German, and Latin, the forms of the words are so altered that they cease to be recognizable. Schleyer's method throughout is extremely arbitrary, and though Volapuk is an advance over the older philosophical languages, it develops its relatively sound basic principles in a very uneconomical and unsatisfactory manner. Moreover, in attempting to make his language universal, for example, in introducing modifications with reference to the Chinese, Schleyer has exceeded the limits of practicability. An international European language is a sufficiently difficult achievement, and Schleyer has to a considerable extent sacrificed usefulness to a vain longing for universality. Finally, Schleyer was not sufficiently systematic in establishing his principles and in adhering to them, with the result that his language is often as arbitrary and as exceptional as are the natural idioms.

Perhaps the greatest service of Volapuk to the study of artificial languages was the demonstration it gave of the practicability of such a language. It was followed by numerous other experiments, most of them very short-lived. An important advance was not made until the appearance of *Esperanto* in 1887. This language was the invention of a Russian physician, Dr. Zamenhof, whose youth was passed in a village in which four different and antagonistic languages were spoken, Russian, Polish, German, and Hebrew. As a schoolboy Dr. Zamenhof was stirred by the ideal of an inter-language, and *Esperanto*, as it finally appeared, was largely the outcome of these early humanitarian impulses. The interest in *Esperanto* at first spread slowly, but enthusiasts gradually gathered in support of it, and it soon came to have more adherents and students

than any artificial language before it had acquired To-day it shares with its successor and rival, *Ido*, or the Idiom Neutral, the place of eminence among artificial languages

So far as its grammar is concerned, the ruling principles of Esperanto are simplicity and regularity The alphabet consists of twenty-seven letters, five vowels, and twenty-two consonants, each of which has a constant and single value, the vowels being given what is known as their Continental or Italian pronunciation Esperanto is thus phonetically regular The symbols used are the familiar ones of the Roman alphabet, but five consonant symbols are used twice, with the awkward device of diacritical marks placed over the respective letters to indicate their special values Thus *g* = the sound in "good," *ĝ* = the sound in "gem" The accent of words is fixed, and falls always on the penultimate syllable Specific endings indicate the various parts of speech substantives always end in *-o*, adjectives in *-a*, derivative adverbs, *ie* those derived from words which appear also as nouns and adjectives, in *-e* The definite article is *la*, it is indeclinable, but the syntactical rules for its use are somewhat complicated The language has no indefinite article, the indefinite idea being assumed from the lack of definition

Nouns are inflected for the plural number by adding *-j* (= *-y*) to the singular, and for the accusative case by adding *-n* to the singular or plural form of the nominative Adjectives are inflected like nouns The nominative singular, therefore, of the phrase "the good father" would be *la bona patro*, the accusative *la bonan patron* The plurals, nominative and accusative, would be *la bonaj patroj*, and *la bonajn patrojn*, the adjective agreeing with the noun in inflection Comparison of adjectives is expressed analytically by means of separate words of comparison, like English *more*, *most*

The personal pronouns are *Mi*, I, *Vi*, thou, *viu*; *Li*, he, *Ŝi* (pronounced like English *she*), she, *Ĝi* (*g* soft as in *gem*) it; *Ni*, we, *Ili*, they The indefinite "one," German "man," is *oni*, and the reflexive pronouns for all genders and numbers is *si* The accusatives of all these pronouns are formed as in the nouns by adding *-n* Possessive pronouns are formed from the personals by making them adjectives, that is, by adding *-a*

There is only one conjugation for the verb in Esperanto, which is therefore completely regular Inflections are used to indicate tense and mood, person and number being expressed only by the subject of the verb The inflection of the infinitive is *-i*, *ami* = to love; of the present tense, all persons and numbers, *-as*, *Mi amas* = I love, *Ili amas* = they love; of the past tense, *-is*, *Vi amis* = you loved, *Li amis* = he loved; of the future, *-os*, *Mi amos* = I shall love, *Li amos* = he will love, of the conditional mood of verbs, *-us*, *Mi*

*amus* = I should or would love, of the imperative, also of the subjunctive, *-u*, *Amu* = Love, *Li finu* = Let him finish, *ke mi amu* = that I may love Three participial forms, *-anta*, present, *-inta*, past, and *-onta*, future, are used for the participles of the active voice, which can be used as nouns, adjectives, or adverbs by taking the proper endings There are also three passive participles, *-ata*, *-ita*, *-ota*, subject to the same rules as the active participle. These participles are used in the formation of verb phrases like those of English grammar

Prepositions are followed by the nominative and not the accusative case Adverbs, prepositions, and conjunctions, *ie* the particles in general, are less reducible to simple type forms than the other parts of speech, and consequently this part of Esperanto grammar is likely to seem more difficult and artificial than the rest Many of the forms also seem strange, *e g krom*, except, without, *kial*, why; *kiam*, when, *tial*, therefore, etc The word order of Esperanto is logical, and very similar to that of modern English

In its vocabulary Esperanto is based upon a relatively small number of root words, chosen according to the sound principle of the maximum of internationality A first group of words is made up of roots which are of the highest degree of internationality among the European people, *e g atom*, *aksiom*, *form*, *flut*, *fosfor*, *teatr*, *tabak*, etc (in the spelling of Esperanto) Another group consists of those which are only partially international, but which are chosen for their places in the international language because they are used by the larger number of European languages. By a similar process of selection the whole vocabulary is thus built up on this principle of the maximum of familiarity or internationality It should be observed, however, that this root vocabulary is not concerned with questions of etymological origins in the various national speeches Thus the English language is assumed to possess the root word *vir-*, "man," because it has the adjective "virile" The guiding principle in the selection of the roots has been their intelligibility, not their etymological history Besides its vocabulary of international roots and its inflectional system, Esperanto also makes use of composition or agglutination in the formation of words Thus the prefix *mal-* indicates the contrary or opposite, *e g amiko*, "friend," *malamiko* "enemy"; the suffix *-in* indicates the feminine, *e g viro*, "man," *virino*, "woman," *patro*, "father," *patrino*, "mother"; *-et* indicates the diminutive, *e g monto*, "mountain," *monteto*, "hill," etc

Esperanto has suffered the usual fate of artificial languages in that it has had to meet with the opposition of a rival language, in this case *Ido*, or Idiom Neutral *Ido* was promulgated by the *Delegitaro por Adopto de Hel-panto Lingvo Internaciona* (Delegation for the

Adoption of an International Auxiliary Language). This Delegation resulted from the Paris Exposition of 1900, and was self-constituted, its purpose being to decide which of the various international languages should be generally accepted as the standard one. Endeavors were made to have the International Association of Academies assume the responsibility of deciding this question, but this organization refused to do so by a vote of twelve to eight. The Delegation then constituted a committee of twelve, which met in 1907, with the distinguished scientist, Professor Ostwald of Leipzig, in the chair. This committee unanimously decided that the best language was a modification of Esperanto, presented by M. de Beaufront and known as *Ido*. Overtures were made to the *Lingua Komitato* (Linguistic Committee) of the Esperantists, looking toward the cooperation of the advocates of Esperanto and *Ido*. The Esperantists, however, refused to join forces with the Delegation, and *Ido* consequently now presents itself as an independent claimant for recognition as an international auxiliary language.

Accepting in general the principles of Esperanto, *Ido* differs from it only in details which its supporters regard as improvements suggested by experience. For example, *Ido* does away with the diacritical marks of the Esperanto alphabet, and uses only the twenty-six symbols of the English alphabet. It likewise dispenses with the accusative case of Esperanto, on the ground that case is sufficiently indicated by word order, as in the English language, which has no case forms except a few survivals in the system of the personal pronoun. It further advocates a number of modifications and extensions of the vocabulary of Esperanto. In general the reforms of *Ido* may be regarded as carrying to a higher degree of simplicity and effectiveness the principles of Esperanto.

Several questions suggest themselves as to the future of international auxiliary languages. It seems at present impossible to say which one, if any, of the languages now competing for the honor will be generally accepted. On the other hand, there seems little reason to doubt that in course of time some one international language will meet with general acceptance and will be used for the purposes to which such a language can be put. Some of the best linguistic thought of modern times has been expended on the subject, and the improvement of such a language as *Ido*, for example, as compared with Volapük, has been very great. An artificial language, being the result of human theory and ingenuity, must necessarily perfect itself gradually, and the reproach of impermanence which is frequently made against all such projects may as justly be urged against international arbitration, or peace, or any other formative idea.

**LAPSES** — Inappropriate responses to a given situation, especially in speaking and writing, and occurring in that condition of attention known as absent-mindedness. If attention is regarded as the focal point of consciousness, the lapse may be considered as due to the relationship between the focal point and the margin. Proper adjustment to environment requires not only concentration of consciousness at one point, but a proper relating of the marginal elements. If this is not the case, the result is absent-mindedness. Absent-mindedness may be due to two quite different phases of the attention process. In the first place, the attention may be so concentrated at one point as to neglect to too great an extent the marginal elements (abstraction). In the second place, the absent-mindedness may be due to too little concentration, that is, dividing of the attention (distraction).

In speaking and writing we carry on a number of more or less separated activities at the same time, the attention usually being occupied with the thought of expression, and the expression itself being cared for by the more or less automatic processes controlled by the marginal elements of consciousness. Frequently, when the attention is concentrated or distracted, these two processes interfere with each other, and lapses result. An example is frequently to be found in the schoolroom, when the teacher, in asking a question, inadvertently gives the answer to the question. It is to be noted that the person making the error is frequently unaware of the fact, and never aware of it until after it has occurred. It is the result of involuntary processes, due to the

causes mentioned above. Fatigue, hurry, and nervousness often are inducing causes of lapses, and some persons are much more inclined to make them than others. Lapses have interesting similarities to the phenomena found in aphasia (*q.v.*) E. H. C.

**LASALLE COLLEGE, PHILADELPHIA, PA**  
— See CHRISTIAN BROTHERS

**LASALLE, ST. JOHN BAPTIST DE** (1651-1719) — Founder of the Institute of the Christian Brothers (*q.v.*). Born of a noble family at Rheims, he early showed a highly spiritual and devotional temperament, and at the age of eleven received the tonsure. In 1667 he was installed Canon of the Cathedral at Rheims. He studied at the local university, and took his M. A. in 1669, and then proceeded to the Seminary of Saint Sulpice in Paris, where he also attended lectures at the Sorbonne. The students at the seminary were required to help the director in catechizing a large number of children, and the questions of method were frequently discussed. In 1678 Lasalle entered the priesthood. Inspired by the enthusiasm of his spiritual director, Nicolas Roland, he succeeded him in the general supervision of the Congregation of the Sisters of the Child Jesus, which conducted a free school for girls, although on his own confession he was not greatly interested in education. It was almost by chance that he undertook the great educational work which gives him an important place in the history of education. A relative living in Rouen requested him to assist in the opening of a free school in Rheims, of which Adrien Nyel was the master. The success of this school led to the foundation of others, until there were five masters in the town. Lasalle soon discovered that in spite of himself he must take an interest in the welfare of these men, and, acting at first as their adviser, he decided before long to resign his canonry and his worldly possessions and live with them. In 1681 a house was purchased, and the foundation for the Institute of Christian

Brothers was laid. A rule was drawn up, which was the basis of the later rule; new teachers joined the community, and the demand for the *Frères des Ecoles Chrétiennes* rapidly increased. Unable to satisfy any requests but those from towns, he undertook to train boys who were sent to him by the country clergy and who were to return to their homes after their period of training. A novitiate had already been instituted, more by accident than by design. In 1688 Lasalle accepted a call to Paris; in 1691 a house was rented at Vaurigard, near Paris; and in 1693 the Rule was drawn up as now known. In 1695 the *Manual* was issued. Christian Brothers were requested to take charge of the schools of several parishes. The work of Lasalle himself, however, was not confined to the elementary schools. He personally took charge of a Sunday school for young artisans under twenty, and taught them mathematics, mechanics, drawing, and other vocational subjects. After the English Revolution (1689) he was requested by Louis XIV to take charge of a number of Irish and English Catholic boys of good families. But the extension of his work in Paris brought him into conflict with the established order of writing masters and schoolmasters, and as a result of a lawsuit, he was forbidden to open schools in Paris without the permission of the Precentor (1705). Further, he was not immune from ecclesiastical jealousy, and attempts were made to remove him from his position as Superior of the Brothers. In 1705 he opened at St. Yon another house, which was destined to become the mother house of the Institute. In 1712-1714 he traveled in the south of France, visiting the houses of the Christian Brothers and novices. In 1716 he resigned as Superior, and was succeeded by Brother Barthélemy. In 1719 he died at Rouen.

On French education Lasalle and his Institute exercised the greatest influence in introducing a better class of teachers and a better conception of schools and instruction. How far his influence went outside of France it is impossible to say, but many of his reforms in education were certainly reintroduced or rediscovered later. For a detailed account of his educational work and theory, and a list of his writings, see CHRISTIAN BROTHERS and the references there given.

**LASCARIS, CONSTANTINE** (1434-1501) — A Greek teacher of the Renaissance period. He belonged to a noble family, and until its

capture by the Turks lived in Constantinople, afterwards finding a refuge in Corfu and Italy. He was Greek tutor to the daughter of Francesco Sforza at Milan, taught at Rome with the support of Cardinal Bessarion, and in Naples at the request of Ferdinand I. For a time he was also in Spain. The last thirty-five years of his life he spent as a teacher of Greek at Messina, where he numbered the future Cardinal Bembo (*qv*) among his pupils. His chief work was the *Grammatica Græca sive Compendium octo Orationes Partium* (1476), probably the first Greek work known to have been printed. This *Grammar* was much used in schools. Lascaris also collected and copied many Mss. His collection, which was left to the Senate of Messina, was placed in 1712 in the National Library in Madrid.

**LATIN LANGUAGE AND LITERATURE, IN EDUCATION.** — **Historical** — The history of Latin in the schools is practically the history of schools, at least of all schools above the most elementary character, from the closing centuries of the Middle Ages until well into the nineteenth century. The secondary school was the dominant school throughout all this period and in almost all cases they were Latin schools. To such an extent was this true that the terms by which they were known, Grammar Schools, Public Schools, Free Schools, Gymnasien, Lycées, Colleges, were practically all synonymous with Latin School. Until the nineteenth century Latin was practically the only subject; that is, all other subjects were studied incidentally and through the medium of the Latin language and literature. Greek might be added, and in some cases in the eighteenth, and quite generally in the nineteenth century, mathematics. Hence the historical aspect of Latin in the schools is treated at length in various articles. The entire scope of the subject is included in the article on GRAMMAR SCHOOLS. The articles on GYMNASIUM and LYCÉES give

other aspects of this subject, as do also in a less direct way those on ACADEMY, COLLEGE, and UNIVERSITY. The article on the RENAISSANCE AND EDUCATION treats of the formulation of the secondary school as it was given the Latin form in which it has dominated throughout the modern period; that on education during the Middle Ages, its place and function in the earlier period. For a detailed statement of the place of Latin language and literature in the educational systems of the nineteenth century, see the sections on Secondary Education in the various articles on the national systems given under the caption of each nation.

The following sections relate to the development of the school material connected with the subject, and the scope and method of the subject in the present.

**Latin-speaking** — As ancient Rome had endeavored to establish a universal Empire, so the medieval ecclesiastics attempted to organize a universal Church, within which there should be the uniformity of dogma, of Church ritual, and along with it uniformity of language in which divine service should be conducted, viz. Latin. With the various dialects into which the Latin was broken up in Spain, France, Italy — there was only one standard to which appeal could be made for intelligibility, viz. the ancient Latin, as contained either in classical authors, in the Vulgate copy of the Scriptures, or in the tradition of spoken Latin, mainly if not entirely centered in the ecclesiastics. When the new enthusiasm of the Renaissance came, with the fresher knowledge of Latin and Greek authors, the need of the Latin speech as felt in the medieval period was emphasized, the real change being the recognition of the necessity to substitute classical Ciceronian language for the old monkish jargon and barbarism which had been developed in the long course of medievalism. So, in 1516, when Bishop Fox founded Corpus Christi College, Oxford, by statute, he required his first lecturer, "the sower and planter of the Latin tongue, to manfully root out barbarity from our garden, and cast it forth should it at any time germinate therein." Besides reading classical authors, Bishop Fox directed his lecturer to read to all who wished to hear him the *Elegantia* of the Latin Tongue, by Laurentius Valla, who had described Latin as the "sacristy of erudition." He had embodied the opinion of all the scholars when he said that since Latin is the treasury of learning and the instrument of conversation, it should be the *one language* in common use amongst all nations. It was clear that all Christians initiated in the same religious duties must use it. It was often pointed out that the diversity of languages was due to sin, and the return to a unity in language seemed therefore to have a certain religious implication. There would be a confusion of all kinds of knowledge if different languages were used, owing to men's ignorance of many languages. The enthusiasm of

the Renaissance led to the ubiquity of students, and Latin followed in their train. Thus it is said that hotel keepers and merchants had to adapt themselves to some sort of Latin speaking and beggars moaned out Latin tags in their appeals to student passers-by.

In the earliest statutes (1274) of an Oxford college, viz. Merton College, it is laid down for scholars "when they speak they must use the Latin language," and in its use defer to the direction and correction of the grammar master. In Queen's College, Oxford (Statutes, 1341), scholars had the choice at table of Latin or French, and only out of politeness to a visitor were they to speak the vernacular. In 1556, Trinity College, Oxford, made the requirement that all public conversation, especially amongst scholars, was to be in "a learned tongue." It may be mentioned that about 1705, when Dr. Woodroffe proposed that Gloucester Hall (afterwards Worcester College) should become a specially Greek College, the requirement was suggested that for two years students should converse in ancient Greek and then learn Latin and Hebrew. Similarly, at Cambridge colleges, Latin was required as the language of conversation, until the great Civil War. Wordsworth (*Scholæ Academicae*, p. 90) points out that though Latin ceased to be used conversationally in college halls, yet it continued to be used as the language of college lectures, disputations, and on official occasions. He further states that Adam Smith was the first to lecture in English at Glasgow University, though it seems probable that Dr. Hutchison had done this in 1727. The registers and annals of the College of Physicians were kept in Latin up to the end of the seventeenth century. Physicians made Latin notes of cases, and still prescriptions in England show marked traces of the old Latin in dealing with the pharmacopæia. The annual Harveian oration in the College of Physicians of England was given in Latin till 1865. As recently as 1874 the retiring proctor at Cambridge gave his speech in Latin. And still, on public occasions, the public orator in the English universities gives his speeches at presentations for honorary degrees in Latin. Fulbecke, in the *Preparative to the Study of Law* (1600) and Doderidge in his *English Lawyer* (1631) expect the lawyer to have ability in Latin "clear and neat style," and to avoid barbarisms. James Whitlocke, a judge on circuit, going to Chester, was met at Whitechurch by many gentlemen of Shropshire and Cheshire, and had a Latin oration made to him at the marketplace. The Council of Trent in 1562 required that preaching should be in the vernacular, which points to a survival of a previous practice of preaching in Latin. In 1564, when Queen Elizabeth visited Cambridge, Dr. Perne preached a Latin sermon before her in King's College Chapel. M. Massebieau quotes from M. Haureau to show that sermons in Latin were frequent abroad. Such a statement does not

hold of England except in university sermons and sermons *ad Clerum*. Candidates for the degree of B.D. in the University of Cambridge were required to preach once in Latin and once in English at St. Mary's Church (George Peacock, *On the Statutes of Cambridge*, p. 12). In 1635 Cornelius Burges preached to his fellow Puritan ministers of London in Latin. William Bedell, while at Venice (1607-1610) as chaplain to Sir Henry Wotton, wrote his sermons in Italian and in Latin. Previously, in the time of the Marian Persecution (1553-1558) the chief English exiles in Strassburg, Frankfurt, and Geneva spoke with foreigners mainly in Latin.

Ambassadors ordinarily spoke Latin, but in 1659 John Pell spoke Latin to a burgomaster, who told him he had given over speaking Latin "these fifty years," though in 1660 Edward Leigh in his *Advice on Travel* states spoken Latin to be a necessary part of the equipment for the Grand Tour of travel. (See *Cambridge History of English Literature*, Vol. VII, p. 314.)

When the Nonconformist Academies (*qv*) were established, lectures were given in Latin, and it is said that Dr. Doddridge was the first to introduce the use of English for the regular lectures in 1730.

But quite outside of the higher institutions of learning, Latin speaking must have been common in medieval and Renaissance times. As Mr. Leach says with regard to pre-Reformation knowledge of Latin: "The diplomatist, the lawyer, the civil servant, the physician, the naturalist, the philosopher, wrote, read, and to a large extent spoke, and perhaps, thought, in Latin." He suggests further that Latin was used by merchants, the bailiffs of manors, town and guild clerks, generals, travelers, architects, all of whom needed a knowledge of Latin as a spoken as well as written language. In other words, before the Reformation England was to a large extent bilingual, every educated man, as it has been said, "knew something of the language in which he said his prayers." The one profession was the Church. This was the democratic outlet, for advance in a Church career was a poor boy's chance, whether he was to become a diplomat, a lawyer, or even a physician. Boys were brought up in the chantry of a church, *i.e.* within the church building itself, and breathed the atmosphere of Latin. The Renaissance intensified the importance of Latin for children, but insisted on pure Latin instead of the medieval barbarism. Erasmus, Vives, Sir Thomas Elyot, regarded Latin as the one language by which a child could become well instructed both in literature and all sciences. (See Sir Elyot's *Governour*, Croft's Edition, Vol. I, pp. 33, 54, 116.) The child should be surrounded by parents, tutors, servants, all of whom should speak to him only in Latin. For an instance of such family training see Cor

derius' *Colloquies* (Bk II, *Colloquy* 50), said to refer to the household of Robert Stephanus, and the well-known case of Montaigne. Latin speaking became at any rate the mark of a gentleman's training, and important for all who contemplated foreign travel. There is the extraordinary case of Robert Gentili (1590-1654), son of the famous Perugian lawyer Alberico Gentili, educated in England. He always spoke to his father in Latin, and his mother in French, and at seven years of age it is said he could speak both languages as well as English. But his after career did not add credit to the educational prodigy.

The Reformation made Latin speaking less important for the ordinary child, because services took place in the vernacular. But for the educated and for the intelligent Protestant, Latin speaking was still essential, for those who read Calvinistic foreign writers, and wished to be in touch with foreign thought. The Exile-Reformers were permeated with the educational views of coreligionists abroad, and the leaders in the reign of Elizabeth introduced the requirement of Latin speaking into the school statutes. In the writer's *Grammar Schools up to 1660* (pp. 316 *et seq.*) are given representative instances of the requirement of Latin speaking in the statutes of English grammar schools from 1524 to 1664.

In Malm's *Consuetudinarium* for Eton College in 1560 a boy was to be named as a *custos* if he was detected talking English in lesson time and for other school lapses. The name was originally given to the boy in each form who had to repeat the lessons first and to answer questions, and it is suggested by Maxwell-Lyte that it came from medieval times by analogy to the *custos chori*, whose duty was to begin the singing in church -- as the school *custos* was to begin the repetition in school. In 1621-1628 the *Consuetudinarium* of Westminster School required monitors, "Two for the Hall, and as many for the Church, the School, the fields, the cloister, which last attended them to the washing and were called *Monitores immundorum*. The captain of the school was over all these, and was named *Monitor Monitorum*. These monitors kept boys strictly to the speaking of Latin in their several commands," it was their duty to present "complaints or accusations" every Friday morning. At Houghton-le-Spring (1574) the boys thus appointed were called *Impositors*, and held duty from Friday to Friday. Custodes, Monitors, and Impositors, as checks on lapses into English speaking, became a frequent institution in schools, and within the memory of those still living there were similar checks against speaking Welsh instead of English in some Welsh schools.

As to the method of training in the speaking of Latin, John Brinsley (*q.v.*) devotes Chapter XIX of the *Ludus Literarius* (1612) to a detailed statement. The criticism there made of Latin speaking in the schools is not that it is

not attempted, but that the boys speak "in barbarous phrase," and do not "utter their minds in Latin easily, purely, and freely." Brinsley objects to the ordinary school practice that Latin speaking should not be delayed, for fear of barbarisms, till the third, fourth, or fifth forms, but should be begun from the first entrance into "construction." The first Latin reading books and authors should be chosen for the purpose of teaching correct Latin speaking. Hence the employment in the school of the *Confabulationum pueriles* or *Children's (Latin) Talk*, and the *Colloquies* of Corderius (see COLLOQUIES). Children "should then begin to practice to use those phrases which they there learn." Brinsley further notes that the reason the Latin grammar is written in Latin and not in English is "only or chiefly to train up scholars to *Deliver* all their Grammar rules and matters concerning Grammar, in Latin." The methods to be employed in teaching Latin speaking are given in full by Brinsley. All examination of grammar rules and reading of authors should be questioned out closely and answered at first in both English and in Latin, until the pupils can answer in Latin alone. What the pupil is unable to answer in Latin, "utter you ever before them, that as the child learneth of the mother or of the nurse to begin to speak, so they may of you and of their author," in Latin. The daily use of the reading of dialogues out of English into Latin, "is nothing but such talking," and may be supplemented by the master "speaking in Latin easily and purely even in ordinary matters." For from the dialogues -- like those of *Confabulationum pueriles* and Corderius, children can speak not only of what is there included but also form talk modeled on them for themselves. In parsing the dialogues, *i.e.* construing and parsing them, they should further "talk" them, uttering every sentence *pathetically*, to one another, first in English, then in Latin. The early stages of Latin speaking thus acquired, Brinsley requires class work in parsing, etc., questions and answers to be in Latin by teacher and pupil, other exercises are grammatical disputations, use of variety of phrases, and further and harder dialogues. But "warrantable and pure phrase," in which lies the solution of Latin-speaking, consists in "practice in a good way," and Brinsley adds, "as in all the rest, is that which doth all."

One of the projects of the seventeenth century in connection with training in Latin speaking was described by Eilhardus Lubinus in 1614 as the setting up in each country of a *Cænobium*, or Community, in which there should be those who had the pure Latin accent and speech, and who should be attended by servants and attendants, even kitchen scullions, who also spoke pure Latin, so that pupils could go and learn no less quickly and perhaps no less certainly than formerly in the Forum Romanum. By residence in such a colony for two or three

years, sound Latinists might be produced, Lubinus thought, "profitable to mankind and in it to the distressed Church of God." Lubinus's views were translated into English, and published by Samuel Hartlib in his *True and Readie Way to Learne the Latine Tongue* (1654). One of the Sloane Mss in the British Museum Library contains a letter of Thomas Horne, written to Samuel Hartlib in 1652. Horne suggests that the charges commonly bestowed on public schools should rather be laid out for the planting of Roman, Grecian, and Hebrew colonies. And Latin-speaking foreigners should be brought to England, Poles, Germans, French, Spaniards, Italians, "who speak Latin well and must be induced to speak no other."

Abroad, Latin was spoken, as Alfred Frankhn says: "Le Latin était la seule langue reçue 'au pays Latin,'" and he quotes a letter of Gui Patin, of May 24, 1650, in which the writer says: "J'ai été aujourd'hui au pays latin, qui est l'Université."

Another description of the training in Latin speaking may be found in Hoole's *New Discovery of the Old Art of Teaching School* (1660). Latin speaking as a school training gradually declined after the commonwealth period in England, though J. T. Philipps urged enthusiastically more Latin speaking and less grammar teaching in his *Compendious Way of Teaching Ancient and Modern Languages* (1727).

There is now a tendency to return to the direct method of teaching Latin, and, at least to some degree, of Latin speaking. One of the best expositions of the latest English methods in this direction is Dr. W. H. D. Rouse's *Latin and Greek*, Section VII of Professor J. W. Adamson's *Practice of Instruction* (London, National Society's Depository, 1907).

F. W.

**Latin Grammars, Vocabularies, and Teaching Apparatus** — *Dictionaries* — Vocabularies with the English as well as the Latin were an earlier form of teaching equipment in England than the grammar. A collection of vocabularies, word glosses, and glossaries from Mss. extending from the eighth to the fifteenth centuries was made by Thomas Wright and privately printed in 1857. In 1884 this collection was reedited and published by R. P. Wulker. Among the vocabularies thus brought to light by Wright are Alexander Neckam's *Treatise De Utensilibus* of the twelfth century and the *Dictionarius* of John de Garlande of the thirteenth century. Neckam's book consists of Latin terms for all the ordinary avocations and occupations of men and women, with a continuous interlinear gloss of explanations in easier Latin, in French, and in English. It is conjectured that the explanations were for the use of the schoolmasters, whose Latin knowledge might need support and suggestion. The vocabularies with their words grouped round subjects instead of being arranged alphabeti-

cally, were rather lesson books than dictionaries in the modern sense. John de Garlande's *Dictionarius* gives the Latin names for parts of the body, and for trades and manufactures. He then described the house of a Parisian citizen and its furniture, his own wardrobe, the Church and its priest, and various other occupations. Dean Nowell, in the Statutes for Bangor Friar School, in 1568, describes the method for use of vocabularies, which probably had gone on for centuries previously. "The schoolmasters shall every night teach their scholars then Latin words with their English significations." After practicing them, the boys are to appear the next morning with the words and meanings retained in memory. In 1580 the Harrow rules explicitly state that "three words" are to be given each night — but they probably mean the words clustering round each subject, e.g. parts of the body, diseases, virtues, vices, herbs, fishes, trees, etc.

Apparently the earliest printed vocabulary was that of John Stanbridge, c. 1500, and this book continued in use as late as 1630, the latest revision having been made by John Binsley, the author of the *Ludus literarius*. The vocabulary developed into the dictionary form. The first Latin dictionary of Renaissance times was that of Ambrosius Calepinus, published at Reggio in 1502. Calepinus made a great collection of Latin words from Latin writers, and included meanings in Italian and other languages. Eventually the dictionary was not only Latin, but polyglot, containing in its greatest expansion eleven languages. From Calepinus Robert Stephanus adopted a *Dictionarium*, in Latin and French, in 1531. This was the first great Latin dictionary to illustrate the force of words in idioms and to indicate shade of meanings of words as used in various writers. It was quickly followed, in 1535, by *Observationes in M. Tullium Ciceronem*, a dictionary of words used by Cicero, written by Marius Nizolius, generally known as the *Thesaurus Ciceronianus*. Laurentius Valla's *Elegantiarum linguæ Latinæ libri sex* in 1471 and the *Cynecopia sive linguæ Latinæ Commentarii*, 1489, of Nicholas Perotti, though gladly used as dictionaries by happy owners, were rather essays in philological and literary criticism on a large scale. But such crude criticism was overshadowed by Julius Caesar Scaliger in his *De Causis Latinae Linguae*, 1540, in which he claimed to enumerate 634 errors in Valla. Erasmus wrote books which were used for teaching purposes. Of the dictionary kind were the *Adagia*, the first form of which appeared in 1500, the *Copia Verborum* in 1511, the *Parabola sive Similia*, 1513. The *Colloquia*, 1516 (see COLLOQUIES), was perhaps Erasmus's chief schoolbook, but it is not of the dictionary type. The *Adagia* were proverbs in Greek of which he gave a translation and exposition. The *Copia Verborum* supplied variety and fullness of language for composition instead of the old barbarisms

and inelegancies. The *Apophthegmata* of Erasmus was not published till 1531. It was not till 1538 that in England was produced a Latin dictionary, that of Sir Thomas Elyot. Elyot states his indebtedness to the old collections of words of Festus, Varro, Nonius, Nestor. Of the moderns, he had taken from Laurentius Valla, Perotti's *Cornucopia*, the Italian "trial," Calepin, the Spanish Antonius Ælius Nebrissensis (*Dictionary latinus-hispanicum et hispano-latinum*, 1532), the French Guillaume Budé (*Lexicon græco-latinum*, 1530). In 1565 Thomas Cooper, at one time Bishop of Lincoln, compiled his *Thesaurus* based on Elyot and on Stephens. This was followed by the Latin dictionaries of E. Grant, 1581, based on Jean Crespin (Geneva, 1562), Rudolph Waddington, grounded on Stephens and Véron, 1584. John Minsheu's *Ductor in linguas*, a polyglot dictionary including Latin, followed in 1599. John Rider and Francis Holyoke produced their notable Latin dictionary in 1617, in which Philemon Holland helped. This was improved upon by Holyoke in 1633, in his *Dictionary Etymologicum Latinum*. But it was in 1677 that Holyoke's son Thomas completed the large dictionary proudly asserted to be "the most complete and useful of any that was ever yet extant in this kind."

But dictionaries were for scholars and schoolmasters, ordinarily not for pupils, though Hoole in 1660 places them among reference books to be kept for use by the scholars. There was published, however, a *Short Dictionary for Young Beginners* by John Withals, the earliest edition of which is traced to 1556. This was essentially an English-Latin vocabulary, arranged according to subjects, giving the names of objects clustered together under heads of the sky, elements, winds, birds, the sea, fishes, etc. This book was revised by Dr. Evans, Abr. Fleming, and last by William Clark (in 1634). The later editions confessedly obtained material from the well-known Hadrian Junius's *Nomenclator* (1567). The last editor explains that the order is not alphabetical, because another method enables the grouping of helpful expressions around any object. Thus with the words "night" and "day" can appear the expressions "it is dark," "it is clear," and other sentences, proverbs, and sayings which relate to these topics. The object is to provide the young scholars with materials for Latin conversation. (See above on LATIN SPEAKING.) It is probable, however, that no work in this field was so important in the history of language teaching as the *Janua Linguarum* (1611) of William Bathe or Bataeus (1564-1614), an Irish Jesuit on the staff of the Irish College at Salamanca. The Spanish *Janua* consisted of some 1150 (sentences 1042 to 1100 being omitted) sentences or *centuriæ* in Latin, with a Spanish translation on opposite pages, an *Appendix de Ambiguis*, defining nouns and verbs with various meanings, and an *Index* containing

about 5300 words, based on Calepinus, and giving a translation in Spanish and reference to their use in the sentences. The centuries of sentences are grouped around some central topic, thus, the first five centuries deal with the cardinal virtues, the sixth with human activity, the seventh with peace and strife, and so on, only the last century is built on a different plan. The *Janua Linguarum* was at once accepted as a model, and many other works in different languages appeared, following the lines of Bathe's work, the best known of these is the *Janua linguarum reserata* (1631) of Comenius (*qv*). (See Corcoran, T., *History of Classical Teaching*, Dublin, 1911.) From what has been said of vocabularies, nomenclators, and such dictionaries as this of John Withals, it will be seen that there was plenty of previous material for John Amos Comenius (*qv*) when he came to compile his *Janua linguarum reserata* (which is a vocabulary arranged in topics and sentences about them) in 1631 and his *Orbis pictus* in 1657.

*Grammar* — All through the Middle Ages the instruction had been "direct," for pupils could not afford Mss books, and in many cases even the teachers did not possess them. Ælius Donatus, a grammarian of the fourth century A.D., wrote the one elementary Latin grammar which was in use for a thousand years. For a full account, see C. Thurot, *Extraits des manuscrits latins* (Paris, 1869). But with an oral system of teaching, and with a paucity of Mss even of Donatus's Accidence, teaching material and methods became traditional, and teachers taught largely according to the practice or "use" of the teachers under whom they were themselves taught. The famous school attached to the hospital of St. John at Banbury under the régime of John Stanbridge seems to have established a prestige in method of Latin grammar, and the phrase "after the manner of Banbury School" perpetuated Stanbridge's fame and his method. The other grammars of the middle ages were not simple like Donatus's. Priscian and his subtleties gave way to the still more abstract, metaphysical, and fantastic speculation of Alexander de Villa Dei, and other textbooks, or traditions of them, such as those held up to scorn by Erasmus, e.g. Florista (Ludolf of Luchow), Papias, Hugutio, Michael Modista, and Eberhard of Béthune. Grammar had become a "speculative," not a practical study, and one of the keenest desires of the Renaissance teachers became the unification and standardization of grammar. The earliest printed grammar in England was that of 1481 at Oxford. The next to claim attention is John Holt's *Lac Puerorum*, 1497. Stanbridge and Whyttington supplied many forms of the Latin Accidence, but this made the case still stronger for a uniform grammar. The later most important names connected with the evolution of the authorized Latin grammar of 1540 are William Lily,

Thomas Linacre, John Colet, Erasmus, and Cardinal Wolsey

Lily had been at work on an elementary Latin grammar as far back as 1509, and a letter of Colet in 1520 speaks of the book as an accomplished fact, and as Lily's book, to be used by him as first master of St. Paul's School. A further letter of Colet dated 1513 refers to it as Colet's own gift. The earliest printed copy is that of the *Absolutissimus de octo orationis partium instructione libellus*, published at Basle in 1515, and at Strassburg in 1515. It consists of twenty-one leaves, and contains a preface by Erasmus, disclaiming the authorship, and acknowledging that he had readily made emendations in it, but that it was Lily's composition. The fact seems to be that Colet made the first draft, Lily supplied emendations and probably wrote the syntax, and was commissioned by Colet to mark any further examples for inclusion as they occurred in the reading of classic authors with the boys. Lily meantime sent the little book to Erasmus for suggestions, and the report arose that it was entirely Erasmus's own work. It is to be noted that William Lily died in 1522, so the title of Lily's Grammar is only correct for the part composed before that date. In 1523 Thomas Linacre composed his *Rudimenta Grammatices* for the use of the Princess Mary. As Juan Luis Vives wrote about the same time a scheme of studies for the Princess, and as the two documents were sometimes printed together, the mistake has been made of regarding them as joint authors of a Latin grammar. Linacre's *Rudimenta Grammatices* is not to be compared with his *De Emendata Structura Latini Sermonis* of 1524, a much more elaborate work. Colet died in 1519, but his *Æditio*, as his *Accidence* is called, was not published till 1527. This Latin title must not be allowed to obscure the fact that Colet's grammar is in English. In it is an emphatic statement of the Renaissance view of grammar teaching, of which the essence is that Latin speech was before, and is before, grammar rules. Colet's *Æditio* contains Lily's Syntax in English and Lily's verses to his scholars *De Moribus*. In 1528 Cardinal Wolsey entered the grammar arena, with his *Rudimenta Grammatices* of thirty-four leaves. Wolsey (? 1475-1530) had been a Fellow of Magdalen College, Oxford, like Lily, and, as is sometimes forgotten, had been a master in the Magdalen College School (1498). In the Preface to his *Rudimenta*, he gives his remarkable sketch of studies and methods to be pursued by the masters of Ipswich Grammar School, and evidently his plans were intended as a model for other schools. The "lytell proheme," and the *Accidence* are borrowed whole from Colet, as also are Lily's contributions to Colet's grammar. Other contributors were pressed into the service of the so-called Lily's Grammar, e.g., Thomas Robertson (from 1524 to 1534), master of Magdalen College School, Oxford,

who gave the *Quæ genus* and versifying rules with it.

With these new grammars and the survival of medieval grammars and grammar traditions there sprang up a great diversity in the course of teaching. In 1540 came King Henry VIII's Proclamation that "As his Majesty purposeth to establish his people in one consent and harmony of pure and true religion so his tender goodness towards the youth and childhood of his realm intendeth to have it brought up under one absolute and uniform sort of learning." Hitherto, the King goes on to say, every master had his grammar, and every school, diverse teachings, and "the changing of masters and schools did many times utterly dull and undo good wits." Accordingly he commands that Lily's Grammar is to be used and "none other." The first edition traceable is that of 1542 (two years after the Proclamation) and the exact title of what was constantly called Lily's Grammar is *An Introduction of the cyght partes of speche and the construction of the same, compyled and set by the commandement of our most gracious sovereign Lorde the King* (anno 1542). Contrary to the earlier grammars, this official grammar is in Latin. It is now unknown who were the commissioners to determine the exact contents of the authorized grammar, excepting that it is traditional that Dr. Richard Cox, tutor to King Edward VI, was one of them.

Lily's grammar was thus in supreme authority from 1540 onward. In 1758 it was appropriated as the Eton grammar, and its use in Eton College continued till about 1868. From 1758 to the present its authority has quietly declined and vanished, without enactment. As a business monopoly, Lily's grammar was very valuable, considerable sums being paid for it as "rent." It passed through the hands of Francis Flower and John Batterby to John Norton, and in the family of the Nortons it remained for generations, with license to print granted to the universities. Ecclesiastical sanction was given to it by *Articles of Visitation* of the archbishops and bishops, who inquired if any other grammar was being used in any schools to its detriment. Attempts were made unsuccessfully to upset its authority in Convocation in 1664 and in the House of Lords in 1675.

There were many attempts at emendations of the King's or Lily's grammar, by translations of the Latin parts, by various forms of exposition or "elucidation," by "præxes" on it, and by writings which announced themselves as friendly to it, but as supplementary. Among these were Thomas Granger's *Syntagma Grammaticum*, 1616, John Danes's *Light to Lily*, 1631, John Clarke (of Lincoln), *Dux Grammaticus*, 1633, Thomas Hayne's *Compendium*, 1637, James Shirley (the dramatist schoolmaster), *Via ad Latinam Linguam*, 1649, and Charles Hoole's *Latin Grammar*, 1651, his

*Common Rudiments*, 1651, and his *Easy Entrance*, 1659. In addition to these there were the foreign Latin grammars such as those of Peter Ramus, Antonio de Lebriza, Vossius, etc. In 1641 Thomas Farnaby curiously enough obtained a special authorization for his *Systema Grammaticum*, too learned a work for ordinary school use, and, as is not always remembered, Jeremy Taylor in 1647 and John Milton in 1669, wrote short and easy Latin grammars. Two other Latin grammars had some good points, those of John Brookbank, *A Breviate of our King's whole Latin Grammar vulgarly called Lillie's*, 1660, and Richard Lloyd's *Latin Grammar*, 1653.

The diversity of grammars grew apace. In 1726, the particularly good *Grammar of the Latin Tongue* by Solomon Lowe gives a list of 186 writers of Latin grammars whose works had been or were in use in England at that date. Criticism of the authorized grammar culminated in a work of Richard Johnson, master of the Free School, Nottingham, entitled *Grammatical Commentaries, being an Apparatus to a new National Grammar, by way of Animadversion upon the Falsities, Obscurities, Redundancies and Defects of Lilly's system now in use in which also are noticed many errors of the most eminent Grammarians, both ancient and modern*, 1706.

But controversy was carried further than the question of an authorized grammar. Dr. Joseph Webbe (d. c. 1633) was a physician-grammarians, who enthusiastically urged that Latin as a language was to be learned entirely from Latin authors, independently of systematic and elaborate grammars, authorized or unauthorized. Other writers wished grammar to be taught by an appeal to realistic teaching, a method which Comenius's *Orbis pictus*, 1657, greatly stimulated. The whole history of Lilly's grammar affords the most striking instance of the failure to maintain the use of a particular book by giving it special royal authorization.

Besides dictionaries, grammars, colloquies (*q v*), verse making (*q r*), rhetoric (see *Rhetoric*), the Latin apparatus was chiefly concerned with Latin letter writing, theme writing, and other forms of Latin composition. The great desideratum was the material on which the pupil could express himself in Latin speech and writing, good subject matter and elegant and eloquent phrases and idioms.

The *Adagia*, *Copia Verborum*, and *Apophthegms* of Erasmus had succeeded to the old *Vulgaria* of Horman and others, all of which has been drawn up with the purpose of assisting the "making of Latins." The books to help in the writing of letters were numerous. Among the most important were those of Erasmus and Vives, *De conscribendis epistolis*, and of Englishmen, John Clarke's *Epistolographia*. In theme writing, Aphthonius of the fourth century A.D. was reestablished as an ancient authority for method. For

subject matter Reusner's *Symbolæ*, Lycosthenes's *Apophthegmata*, 1555, and all sorts of books of *Flores*, and sayings from the classics and modern writers, especially on the subject of morals, were the hunting ground of boys for their themes. For phrases and elegant expressions, Valla, Erasmus, Aldus Manutius, and the English collections of *Calhoppiana* (1613) and *Bibliotheca Scholastica Instructissima*, 1633, both by Thomas Draxe, were recommended. In addition, in the seventeenth century came John Clarke's *Phrasologia puerilis*, 1638, Hugh Robinson's *Scholar Wintoniensis Phrases Latinae*, 1658, Thomas Willis's *Proteus Vincetus* 1655, and William Walker's *Dictionary of English and Latin Idioms*, 1670. But the largest in this sort was William Robertson's *Phrasologia Generalis*, 1686, consisting of about 1400 closely printed double-columned pages. Solomon Lowe, in his *Latin Grammar*, 1726, not only enumerated the writers of Latin grammars, but also stated the names of 118 authors of these vocabularies, phrase books, examples, and sententiæ, who were or had been used in England.

The tendency of these analytical products of phrases and expressions was toward isolated scraps of knowledge. This tendency was intensified by the use of compends or epitomes into which every solid subject of study was brought. Francis Bacon was led to call these "epitomes," the "corruptions and moths of histories, which had made excellent histories bare and unprofitable dregs." The theory on which epitomes and the collection of phrases had been based was probably the usefulness of the method when the collections were made by the pupil himself. For the use of paper books in the collection of literary phrases, examples, and commonplace extracts was much older than Ascham, who is sometimes thought to be the first suggestor, and remained throughout the seventeenth and even eighteenth centuries a most valuable method. For in the old English grammar schools the processes of classical training depended largely on the active initiation of the pupil to gain such control over what he read in authors that he should be able to use it again, in new form, from his own independent standpoint of free composition and speech. The employment of highly analytical methods for the sake of copiousness and elegance of expression in Latin speech and composition (which brought into the schools the excellent piece of work of William Walker on the *Particles* in 1663) produced a plethora of books to supply pupils both with subject matter and choice expressions for all manner of subjects on which they had to write. The very development of classical learning brought a state of Latin apparatus, which took away the old Renaissance sense of initiative on the part of the learner by offering him full provision ready to hand to meet all his wants, and was joined with a corresponding degeneracy of

especially the weaker schoolmasters and schools, so common in the eighteenth century F W

See COLLOQUIES; COMMONPLACE BOOK, DICTIONARIES; GRAMMAR, VISUAL AIDS TO TEACHING; also DONATUS; PRISCIAN; LILY, and the other grammarians referred to.

**Latin, Teaching of** — The position occupied by Latin in the curriculum of the secondary school is due primarily to tradition. During the Middle Ages and at the Revival of Learning Latin was the medium of communication in science, literature, and politics. Consequently it was the first and most important element in education, supplemented by Greek and mathematics, it formed the whole curriculum (See GRAMMAR SCHOOLS). In the seventeenth century the native tongue began to form a small part of the course of study. This was followed in the eighteenth century by the modern foreign languages, and in the nineteenth by the various sciences. Practically all the time devoted to them was taken from that allotted to Latin and Greek. The process has continued until now Greek is omitted from the curriculum in practically all public high schools and in most private ones, and Latin has been reduced to modest proportions (See GREEK IN THE SCHOOLS). Latin now occupies about one fifth of the total time of the secondary schools, but it has to maintain itself against vehement criticism and opposition. The critics maintain that Latin is not a "practical" subject, and that the results of Latin teaching are entirely disproportionate to the amount of time which it demands. The defenders of Latin urge two main reasons for its retention in at least its present condition: (1) its value as a mental discipline, (2) its value as a practical subject.

The value of Latin, or of any subject in particular, as a mental discipline, has been much impugned in recent years, particularly by the psychologists, but there is a tendency now apparent to recede from the extreme position in this regard, and there is abundant testimony from unprejudiced observers in all walks of life to the value of Latin as a training instrument. For above every other subject it trains (1) the process of observation, (2) the function of correct record, (3) the reasoning power and general intelligence in correct inference from recorded observations. To this should be added its great value in developing the power of voluntary attention.

The value of Latin as a practical subject has to do particularly with the effect of the language in the cultivation of English style. In the English vocabulary a very large proportion of words in everyday use are of Latin origin, and it has been estimated that two thirds of the Latin vocabulary of the classical period has in some form or other come over into English speech. For the correct use of synonyms in English and the habit of expressing one's thoughts clearly, concisely, and cogently, a

discriminating knowledge of Latin is indispensable, and while not every pupil in the school may be expected to develop a good style, nevertheless he should be given the necessary foundation for it.

When we turn to literature, we find that Latin is influential everywhere — particularly in our classical authors — by allusion, by quotation, by actual domestication. Many of our great English writers are permeated with Latin. We cannot expect that all will desire to feed their minds on the works of our greatest authors, however much we might prefer it, but certainly we should not deprive them of one of the most important elements in their enjoyment should they be so minded.

The criticism of the results of Latin teaching has borne more heavily in recent years, and teachers are coming to realize that this criticism has genuine foundation. There has been, therefore, much discussion as to improvement of method, and many suggestions, particularly by editors of textbooks. It may be said in general that the tendency of these suggestions has been toward greater emphasis upon oral teaching and the testing of acquaintance with the language by the ability to read its ordinary forms at sight. It has been too true that the value of the exercise in translation, which, when properly done, should be very great, has been seriously impaired by the very widespread use of English translations, a practice which results in slow progress on the one hand, and dulled moral sense on the other. Then, too, in most of our colleges the classes, particularly in the earlier years, have been so large that adequate personal attention to individual students has been impossible, and this difficulty is becoming more and more serious in secondary instruction with the rapid growth of our public high schools. Administrative officers have shown a curious disinclination to treat languages with the same consideration that is extended to the sciences. While it is accepted without question that scientific instruction without individual laboratory work under the eye of laboratory assistants is impossible, the equally obvious fact that instruction in languages without similar practice can be only haphazard and slipshod, is either not perceived or knowingly neglected.

Naturally in the teaching of any language we should begin with the essentials of grammar, together with sufficient exercises to insure the complete learning of the forms, and enough of the syntax to make the reading of simple sentences possible. This would be followed by easy reading, and then by more difficult reading, until the student acquires sufficient mastery to read with some ease whatever he would naturally come in contact with. And this is practically (with certain restrictions) what has been followed for centuries in the teaching of Latin. The question has been chiefly as to the nature of the instruction in the first year and

the sequence of reading material. In the main the colleges have dominated the high school curriculum in America by their requirements for admission, and thus we find that for a long period the course of instruction in the high schools has been the beginner's book, a certain amount of Caesar, certain orations of Cicero, certain books of Vergil's *Æneid* (See COURSE OF STUDY). When the high school course has been four years in length, as is the case almost everywhere, one year has been devoted to every one of these four subjects. Where the course is five years, or six, teachers have enlarged it by the addition of Ovid, Nepos, Sallust, and in some cases have increased the time devoted to the beginner's book so as to spend upon it a year and a half.

In recent years there has developed a strong feeling that the prescription of so much reading has a deleterious effect upon the teaching in the schools, and that better results could be attained if there were less definite prescription of authors and more insistence on the ability to translate easy Latin at sight.

The first year of Latin is the most important work in the whole high school curriculum. This importance lies in the fact that the pupil is studying not only Latin, but the phenomena of organic speech. In some schools in Germany and in England the pupil makes his first acquaintance with a foreign language in the study of French, but this practice has not taken root in the United States, and there the first serious study of linguistic expression begins in the Latin classroom.

Let us see for the moment what the problems of the Latin student are, what the English-speaking child will find difficult or unusual. First and foremost, he will be struck by the Latin forms. English is practically a formless language, the few terminations remaining are not sufficient to form a foundation for the careful study of the expression of ideas by means of termination. The pupil will now for the first time have to distinguish between the various cases of the noun and the various tenses and moods of the verb. This comes as a shock to the average English-speaking child, and it requires months upon months of careful and insistent drill before the expression of case relations by changes in termination becomes second nature. For example, in an English sentence like, "The boy strikes the dog with a stick," outside of the *s* in the verb no indication of meaning is given by any termination, and the three substantives would suffer no change in form, no matter what change in meaning might be brought about by transposition. On the other hand, in Latin the syntax would be expressed not merely by the sense, but also by a formal difference in every noun. Furthermore, the pupil would be troubled by even the simplest syntactical structure. An English sentence like, "The father gave his son some money that he might buy the book," is com-

prehensible to the child without any serious mental effort, but in the Latin sentence he must become acquainted with the idea of purpose and its expression and the use of mood to take the place of the auxiliary. This difficulty is immeasurably enhanced when "to buy" takes the place of "that he might buy." Another difficulty which is none the less real is that of pronunciation. For the first time the pupil comes into contact with what is essentially the Indo-Germanic system of sound expression, from which English has seriously varied. Then, too, there is word order and its possibilities in an inflected language. With these difficulties staring him in the face, and with progress made exceedingly slow on account of the necessity of accurate thinking along several lines at the same time, the first-year Latin taxes the patience, the ingenuity, and the skill of even the best of teachers. And in the United States in particular, owing to conspicuous administrative incompetence, the work of the first year is usually in the hands of the most inexperienced teacher.

*The Introductory Work, the Customary Method* — The material is provided in the numerous first-year books, which show almost every possible idiosyncrasy of method. It may be said in general that they embody the carefully thought out schemes of the individual authors. They follow two main lines of presentation, one of which may be called the block system, the other the fragmentary system. In the latter — and by far the most influential — the lessons, particularly the earlier ones, are so divided that fragments of declension and fragments of conjugation alternate with each other, thus, either the nominative singular, or the nominative and accusative singular, or the nominative singular and the nominative plural of the first and second declensions are followed by the present indicative, singular number, or third person singular and plural, as the case may be. Subsequent lessons fill out the paradigms of the first and second declensions and the first conjugation, after which the other conjugations and the remaining declensions are taken up. In the mean time elementary rules of syntax, such as the agreement of the subject and the verb, the government of the accusative case, the ablative of instrument, the ablative of place, the dative of possessor, the objective or possessive genitive, the use of *ut* to express purpose, sometimes the use of *cum* in the sense of "when" are scattered along according to the caprice of the author. The object of thus breaking up inflectional groups is to provide early in the course reading material which will have in itself some reason for existence, and thus avoid the aridity of the old-fashioned textbook. In the former class, the textbook gives first the declensions in their order, supplementing them only by so much of the verb inflection as seems necessary to make the construction of sentences possible; then follow the conjugations in their order. The

earlier exercises from English into Latin and from Latin into English are largely confined to the translation of detached forms. The critics of the first system maintain that it divorces things that belong together, those of the second that it makes the early Latin work not merely dull, but practically hopeless, because the pupils see no evidence of progress. As a matter of fact, the superiority of the first method to the second is merely specious, and the fragmentary acquisition of forms carries with it many evils. A third method of presenting forms, advocated by a few, is what one might call the topical treatment. The pupil begins with the study of a case throughout all its formations, and after proceeding through the declensions he takes up the verb similarly. Every one of these three methods requires a live teacher to make it successful, and practically, therefore, none shows any superiority over the other. Theoretically the second method is preferable, supplemented by the third wherever feasible, the first being the least defensible of them all.

The selection of the material of the first book involves the three divisions of forms, syntax, and vocabulary. It is generally agreed that unusual forms should be excluded, on the principle that only those in most common use are vital, while the unusual ones can better be learned (if learned at all) where they occur. Consequently the old apparatus of rule followed by exception has practically disappeared, and the beginner's book lays particular stress upon the normalities of language. This principle, however, suffers some modification in practice. It is frequently easier to learn the complete series, even though some of the elements are rare, than to break it up into fragments, the effort of mind is often much greater in the second case. The terminations are best learned in groups, even though examples of some of them are comparatively infrequent. Principal parts are best learned complete, though in the case of many verbs certain of them are never found. In the main, however, the principle is sound. In the case of syntax the situation is different. Comparatively little syntax should be given in the beginner's books, and this should be not necessarily the most common, but the most simple, for the learning of forms taxes primarily the memory, while the study of syntax exercises principally the reason. Therefore the indicative constructions should appear in the beginner's books, and only those uses of the subjunctive which make but slight demand upon the reasoning power, such as its use in wishes, in expressions of purpose and result, and little else. It is customary in the beginner's books to devote the last few lessons to the more elaborate constructions; but conditional sentences and the whole body of constructions with *dum* and the like, *quam*, *quominus*, and concessive clauses would better be deferred to the second year. The same is true of the more involved relative constructions.

The choice of vocabulary obviously depends upon the aim of Latin teaching in general. If, it is generally argued, we taught pupils to speak Latin as we did formerly, we should naturally require a colloquial vocabulary, but since our chief aim now is to give the means of reading Latin literature, we must choose the vocabulary with this end in view. A number of beginner's books claim to limit the vocabulary to the words in most common use in Cæsar. This practice is sound, because it has been found that these words are also in common use throughout the literature, while birds and animals, furniture and everyday occupations would leave the pupil absolutely helpless before a page of any Latin author. The size of the vocabulary for the first year should be about 500 words, and the textbooks usually show about that number. But no fixed list of words can be learned completely by all the pupils, and a certain margin must be allowed for forgetfulness, consequently the beginner's book would do well to show a vocabulary slightly in excess of 500.

The exercises in translation are usually divided into Latin-English and English-Latin. Some teachers hold that no translation from English into Latin should be expected until very substantial progress in the learning of forms has been secured, perhaps not until the middle of the year, but the weight of opinion inclines to the view that translation from English into Latin should begin with the first lesson. This work, however, is very much more difficult than translation from Latin into English, and the demands in vocabulary and syntax should accordingly be lessened.

*The Oral or Direct Method* — Dissatisfaction with the results of the traditional method have led in recent years to the employment of the oral or direct method. The advocates of the latter insist that Latin should be taught as if it were a modern spoken language, consequently they follow in general the principles of direct teaching as employed in the teaching of modern languages. Almost from the very beginning Latin is the customary language of the classroom. At the outset short commands and questions having to do with the necessary activities and surroundings of the classroom form the means of instruction. The pupils are required to answer every question in Latin and to follow every command with a statement of what they are doing. As they progress the range of vocabulary is enlarged, but still restricted primarily to the ordinary activities of life. After a little time the teacher tells the class short stories in Latin, explaining the meaning of unfamiliar words in the same tongue and requiring the class to give him back the story in such Latin as they can command. In this method translation, whether from Latin into English or from English into Latin, is practically unknown. This is reserved for the period when the pupil, having obtained a ready

command with the fundamental principles of Latin, is ready to begin that comparison of Latin and English idiom which renders translation so valuable an exercise. Drill in syntax is obtained partly by the oral exercises, partly by written work. To provide for this drill the teacher may require his pupils to embody such and such constructions in the written work, while in the oral work he may have the various ideas expressed first in one fashion and then in another, turned from active to passive, or from the independent to the dependent form. Short narratives composed of independent sentences may be rewritten so as to involve various kinds of subordination. The effect of such training is to make the forms of the Latin language second nature to the pupils, and to reduce the strain upon the memory by constant practice. The method requires a great deal of ingenuity and readiness on the part of the teacher, for every opportunity afforded by any chance remark of the pupil must be improved at once, but in the hand of a competent teacher the results are claimed to be vastly superior to those of the old method. After some months the pupils have a greater grasp of the forms and easy syntax of the language, and are then prepared to go on to serious reading with much greater ease. The chief drawback of the direct method is one of time. The earlier stages require a great deal more time than is required by the old method, but the advocates of the new method maintain that what is lost in speed is more than gained in definiteness and quality of knowledge, and that in the subsequent years the previous delay is much more than made up. One of the important results of this method is that pupils feel that they have a certain control of the language and are thus relieved of the temptation to use unfair means in preparation.

Very recently in the United States an attempt has been made to modify the traditional method by adding to it some of the features of the new method. Recent textbooks give more attention to colloquial features, and the vocabulary of the earlier lessons has to do with the ordinary activities of life. But this choice of vocabulary is intended merely to facilitate the colloquial handling of the language by the pupils, and is expected to give way to the normal literary vocabulary as soon as the serious reading of Latin literature is begun.

*Pronunciation* — Whatever method is employed, the initial difficulty is that of pronunciation. The Roman method is commonly employed. Objections are occasionally made to it but its foundation is secure both in knowledge and in intellectual honesty. It is frequently said that we do not know how the Romans pronounced. This is true only to the extent that those who have not actually heard a modern language do not know how it is pronounced. We have a fairly accurate knowledge of the sounds of the Latin letters, and we have

special directions as to the position of the organs of speech in articulation. While some of these directions come from a comparatively late period, — as late, in fact, as the sixth century A.D., — yet the laws of linguistic development show conclusively that the directions of this period involve certain preceding conditions which can be postulated with accuracy. To determine Roman pronunciation we have, besides the directions of the grammarians just alluded to, transliterations of Greek words into Latin and of Latin words into Greek. We have inscriptional evidence as to the length of the vowels, occasional remarks in Latin literature touching upon pronunciation, and the evidence presented by the Romance languages, which modified in transition the Latin sounds after a definite manner. We are able, therefore, to give in the textbooks the sounds of the Latin letters with practically as much certainty as we can the sounds of a modern language in textbooks for foreign use. To the ear of a Cicero a modern Latinist would speak with an "accent" but he would be understood. It is the business of the teacher to show in pronunciation a careful attention to exact enunciation and to require on the part of the pupils the same accuracy. The pupil should never hear a Latin word mispronounced by the teacher. The Latin that is to be translated should if possible be read aloud by the pupil, and such practice should be continuous. A little careful practice every day is better than a great deal at intervals. The teacher should pay attention particularly to the quantities of all the vowels in his own enunciation and to syllabic division, the pupil, however, should not be forced to learn anything but the quantity of terminations and penultimate syllables. The former should be learned in the acquisition of the forms, the later on meeting with the new word. Inasmuch as Latin accent depends upon the length of the penult, it is not necessary to require a careful marking of the earlier syllables in the word, except, where it is an obvious derivative of a form already known. Hidden quantities, so called, should not be required of the pupils, but the teacher should be careful to pronounce them correctly as far as our knowledge extends.

*The Later Reading* — In many of the older English schools and in those American schools with a curriculum of more than four years, the introductory work extends over into the second year, but in the new English schools and in the vast majority of American schools the reading of genuine Latin begins in earnest with the beginning of the second year. The arrangement of the curriculum for subsequent years differs in different countries. In general Nepos and Cæsar are taken up first, and then a mixed combination, composed mainly of selections from Cicero, Ovid, and Vergil, but with possible substitutions of Livy, Sallust, and Terence, has been the habit. In the United States up to very recently the almost universal practice has been

to devote the second year to *Cæsar*, the third to *Cicero*, the fourth to *Vergil*. The amount of *Cæsar* prescribed (four books) has proved to be a very severe task for the ordinary high school class. It has involved a definite advance every day, and it has thus been impossible in many cases to take account of weak students or to linger for the purpose of securing thoroughness. The plan recently adopted decreases the amount of reading specifically required and lays increased emphasis upon reading at sight and the acquisition of additional vocabulary. (See COLLEGE ENTRANCE REQUIREMENTS.)

The transition from the beginner's book to *Cæsar* is difficult, and the pupil is apt to show a weakness entirely unexpected from the work of the previous year. This is due to the complexity of the periodic sentence. Word order and the various devices of subordination give a great deal of trouble. At the outset the teacher must be content with short lessons in which attention is paid particularly to the new constructions and the new words. He should also devote a good deal of attention to working over the Latin sentence into genuine English. The class should be drilled in the difference between Latin and English idiom, and should be required to translate at least the review passage into correct English. The work done during the class hour should be of two kinds: the work of the previous day should first be reviewed, and the rest of the hour should be devoted to a preliminary sight translation of the work of the next day under the guidance of the teacher. As far as possible, the home work should be restricted to the study of syntax (often in written exercises) and vocabulary. Every now and then the pupils should be required to write out in class the translation of a small portion (if only four or five lines) of the day's lesson, and these written translations should then be criticized by the teacher from the point of view of the English expression. One such exercise is worth a dozen oral translations for the appreciation on the part of the pupil of the difference between Latin and English expression. The teacher must never lose sight of the fact that from the beginning of the second year the most important part of the training is the development on the part of the pupil of the sense of style, by which is meant good English as an offset to good Latin. If the advantage claimed for the study of Latin in appreciation of English style is to be secured, it can only be done in this way.

*Cæsar* furnishes particular problems. In the main his narrative is simple, concrete, narrow in range of ideas, and easily followed. In fact, no author in the whole Latin literature is better suited for the reading of the second-year Latin. But *Cæsar* shows a fondness for the insertion of speeches in what is called indirect discourse. These have nothing to do with the narrative, and could be omitted without disturbance. The length of these speeches in the first book has led many teachers to begin

with the second book. Such a practice is faulty in principle, and,asmuch as the speeches are not necessary to the narrative, it is far better to begin with the first book, and for the teacher either to translate or to paraphrase the speeches as they occur in order merely to give the setting of the story. A good deal of stress has been laid upon the ability of the pupil to turn direct discourse into indirect discourse and the reverse, but it should be remembered that *Cæsar* is the only author whose style is characterized by indirect discourse in mass, and that, so far as the learning of Latin is concerned, the time devoted to the intricacies of indirect discourse would much better be devoted to more extended reading. Nevertheless, until we are prepared to give up *Cæsar*, some attention should be paid to the indirect discourse, and the speeches might well be reviewed toward the end of the year, when *Cæsar's* story is being studied as a whole.

In studying *Cæsar* due attention should be paid to the development of his narrative and to the Roman art of war. Pupils might be required after a campaign to write out an account of it, or they might be required to plan or describe a battle. Some attention may be paid to *Cæsar* as a man, his dealings with his troops, his attitude toward the State, the circumstances which led to the Civil War. But of course these studies should be supplemental merely, for after all, while *Cæsar* is history, he is being read primarily to learn Latin. If the plan of preparation indicated is followed, no particular effort need be made to develop the power to translate at sight, but a period may be devoted, perhaps as often as once a week, to sight translation only. The passage read may be merely a further section of the advance narrative, or interesting passages may be selected from the later books or from any other Latin of approximately equal difficulty.

During this year much attention must be paid to prose composition, and as this important exercise is for the purpose of systematic grammatical study, it should be done systematically from the beginning. The exercises should be graded in difficulty, and should follow a definite plan of syntactical development. They should, accordingly, not be merely based upon a small section of the text. All that can be expected is that the vocabulary should be that of the stage of study and that the style should be narrative. If the subject can be made either identical or similar with what the student is reading, so much the better. It is the habit of many to devote one period a week to prose composition. This is theoretically objectionable. It is better that a short exercise should be done every day. Review exercises embodying a number of principles previously studied may occupy the period every now and then, but one period a week devoted to Latin composition involves too long an interval between efforts. Oral composition in connection with the reading

of the day may often be productive of excellent results.

When some of the *Lives* of Nepos are substituted for a portion of the *Cæsar*, the same general principle should be followed in the teaching, but the supplementary work would of course be different. Nepos is, however, not so suitable as *Cæsar* for this stage, because his vocabulary is much wider and involves many unusual words, and many of the conceptions are abstract. Nor does the brevity of the episodes serve to counterbalance the greater complexity of the periodic sentence.

Ordinarily *Cæsar* is followed by *Cicero*. *Cicero* not only represents the highest point of Latin classical style, but he was the greatest Roman orator and an important figure in the death struggle of the Republic. The orations usually chosen are the four against *Catiline*, the one on *Pompey's* command and the one for the poet *Archias*. The orations against *Catiline* are the easiest of all, and have an important political significance. The *Pro Lege Manilia*, in addition to being a comparatively early speech, marks the beginning of *Pompey's* growth as a great figure, and also forms a good opportunity to study the rhetorical elements in the orator's style. The *Pro Archia* is in effect a eulogy of Greek literature and a wonderful example of the panegyric style. Sometimes the teacher prefers to read a different set of speeches for the purpose of focusing the attention of the pupils upon some particular side of *Cicero's* multifarious career, and many teachers like to substitute for some of the speeches mentioned selections from *Cicero's* correspondence, chosen either to show the great orator's human side or to throw sidelights upon the history of the period. Some teachers regard *Cicero* as dull and uninteresting to pupils, and prefer at least to begin the third year with *Vergil*. This apparently unpedagogical practice is defended on the ground that *Vergil*, even if not thoroughly understood, is interesting on account of the narrative, that his style is not difficult, and that outside of the strangeness of the poetical dress, the narrative moves quickly and easily. Moreover, the syntax on the whole is easier than that of *Cicero*, because of the absence of involved sentences. Others begin the third year with *Vergil*, and after a time they take up *Cicero* completing both *Cicero* and *Vergil* in the fourth year. But this is all pedagogically unsound. *Vergil* should be deferred to the fourth year, because his writings are pure literature, and need for proper appreciation and enjoyment as much maturity of mind as can be brought to them. On the other hand, *Cicero* makes but small demands upon the mental maturity of his readers. In teaching *Cicero* it is proper to go more into detail about the history of the later years of the Republic and the condition of parties at Rome. The work of the *Cæsar* year in this regard might well be amplified, and the attempt made to give the pupils some rational

idea of the workings of the Roman constitution, but the main stress should, of course, be laid upon the interpretation of the speeches themselves. The teacher should possess a great deal of imagination because *Cicero* is serious, ironical, humorous, jesting, or playful in turn, and his invective on the one side is offset by the deepest pathos on the other. Very often the point of the passage depends on the order of the words or the application of a particular word. References that seem blind can be lighted up by modern instances. *Cicero's* personal character and the main facts of his personal life should not be overlooked, and the teacher should try to lead his pupils to some understanding of the man whose soul was torn in two directions, who felt always the conflict between inclination and duty, who followed a sinking cause with his eyes open and remained true to his convictions even at the cost of life.

When *Ovid* is read, whether after *Cæsar* or *Cicero*, it serves as an introduction to Latin poetry and to ancient mythology. It also relieves the early study of *Vergil* of the drudgery usually attendant upon the shift from prose to verse, and makes it possible to treat *Vergil* as literature from the beginning. Selections from the *Metamorphoses* are usually chosen, because the narrative is easy. The chief difficulty is one of word order. To relieve this some editions have the earlier selections rewritten in prose order. Scansion also is a serious exercise for most pupils, even when they have been carefully trained in pronunciation from the beginning. Most teachers are content if some appreciation of rhythm is developed, and pay little attention to the conflict between verse and word accent that regularly obtains in the first part of the verse. Others maintain that, as Latin is a language of almost "level stress," the verse will scan itself, if the words are pronounced as they should be pronounced in prose. Few teachers, however, are able to reach this point of perfection, even in their own scanning.

It has been objected that because the works of *Vergil* represent the highest reach of the Roman imagination and the most finished product of Roman literary art, they should be reserved for the later period of study, when the attainments as well as the maturity of mind of the student are greater. If we were sure that our students were going to continue the study of Latin for some years, this objection would weigh, but the great majority of secondary pupils terminate their study of Latin with the high school course, and it seems indefensible that any should give up Latin after four years' study without having had the opportunity to read *Vergil*.

Since most American high schools prepare for the college examinations at the end of their course, it becomes necessary in the last year to devote considerable attention to a review of grammar and syntax. *Vergil*, however, is not well suited for this. His style is in general

very simple; subordination is conspicuous by its absence, the subjunctive constructions that are so common in all Latin prose are comparatively rare. The syntax of the cases can, it is true, be studied with some effect because most of the so-called poetic usages have to do with case constructions, but these are the easiest, after all, and the pupil needs most to review the construction of the verb. This is best accomplished by the careful writing of Latin during the whole of the last year.

The selection usually read is the first six books of the *Aeneid*. This is justified, first, by its extreme interest for all kinds of pupils, secondly by the fact that neither the *Bucolics* nor the *Georgics* treat matters of universal appeal. The subject and the vocabulary of the *Bucolics* were exotic to the Romans themselves. That of the *Georgics* is too specialized to warrant any great attention on the part of high school pupils. The first six books of the *Aeneid* are without question the most important part of this poem, and they have a world interest which is not so much felt in the latter books.

In teaching Vergil the aims are altogether different from those that dominate the teaching of Caesar and Cicero. Here is no place for the study of military operations, the colonial system or method of government, nor is there any occasion for investigation of party feuds and social relations. Since the Roman epic is a purely literary creation, stress should be laid as far as possible upon the literary element. The ancient mythology, the ancient simplicity of life, the ancient morality, all claim attention, but these are subordinate to the far-reaching literary interest which Vergil exercises upon all subsequent authors. Most of the school editions contain copious parallel passages from later literature. In many cases these are not genuine parallels, and the pupil either gets no impression or only a very vague one from reading them. This ought not to be the case. An attempt should be made to focus the attention of the students upon certain important features of English literature and upon certain particular authors who have been under classic influence. With that in view it would be well to treat at greater length the influence of Vergil upon Shakespeare, upon Tennyson, upon Milton, and so forth. This can be done usually with the material provided in the editions. The pupils should also be taught throughout to visualize the scenes, to form their own judgments as to the narrative in its various stages, to become independent in attitude. Here, too, extreme care should be exercised in translation. Poetic language should be rendered poetically. It will be the first experience of most students in distinguishing what is prosaic in expression from what is poetic, and the fact that Latin verse differs from Latin prose will be better understood if the difference between English prose and English verse is also shown. Images and metaphors should not be washed out. Due

attention should be paid to the artistic setting, the picturesque qualities of every scene. The teacher should never lose sight of the fact that in teaching Vergil he is teaching the principles of literature in general, just as in the earlier years of the course he was teaching universal grammar. In this way Vergil ought to be not merely the proper culmination of the secondary Latin course, but also an important element of the pupil's general culture.

With a longer course Sallust's *Catilina* might be read as a foil to Cicero's *Catilinarians*. Variety may also be attained by selections from Terence or Livy, or by more extended anthologies, a large number of which are now available, adapted to the wants of pupils of different grades.

**LATIN SCHOOLS.** — See GRAMMAR SCHOOLS; PUBLIC SCHOOLS, SECONDARY SCHOOLS, MIDDLE AGES, EDUCATION IN THE

**LATRINES, SANITARY** — Sanitary toilet systems for schools must satisfy the following general conditions (1) They must be situated either in the building or near enough to secure privacy, close supervision, and also to prevent exposure during cold or inclement weather (2) They must have sewer connections and be provided with individual wash-out seats, and urinals In villages and country districts where sewer and water supply systems are not available, the air pressure tank system connected with force pump, manipulated by hand or some form of motor and septic tank disposal ought to be installed (3) Each seat should be furnished with an individual automatic wash-out attachment, in addition to some general flushing system under control of the janitor (4) In all cases where toilets are installed within school buildings, special construction of such rooms is necessary They must have a cement or tiled floor, with outflow connections so that frequent scrubbing and flushing may be secured The walls should be encased with light-colored glazed brick, or tile, both for the sake of cleanliness and the non-absorption of light The ceilings should be furnished with hard cement plaster and painted with a light-colored water-proof paint (5) The seats and urinals should be located along the inner walls of such rooms and faced toward the light (6) Each toilet seat should be in a separate

## LAUD

stall, fitted with doors The custom of building the stalls without doors offends against both decency and modesty These doors ought to be hinged and connected with a spring, so that when the seats are not in use the door will swing back into the stall so as to allow light and if possible direct sunshine to enter The children could then be taught to close and latch the doors when they use the stalls (7) Where toilets are within school buildings, down-draught ventilation through both the seats and urinals is necessary This can be accomplished, when proper plumbing material is furnished, either by an exhaust fan connected with the vent ducts, or by the use of separate exhaust chimneys in which fires are kept burning (8) Urinal stalls should be made with back, sides, and bottoms of white glass Such material is now on the market, and is far better than slate, marble, or transparent glass It is not absorbent, does not discolor, is easily cleaned, and furnishes privacy (9) The flushing of urinal stalls is a matter of importance to prevent odors and insure cleanliness The best form of flushing thus far developed consists in placing a well protected overflow trough on the upper part of the back of the stalls The ordinary perforated pipe is liable to clog and fail in the proper distribution of the water over the entire surface of this part of the stall (10) The bottom of the stall should slope slightly toward the back and deliver into a trough leading to sewer connections This trough ought to be connected in such a manner that rubbish could not enter (11) In large buildings, especially those of more than two stories for high schools or grammar grades, toilet facilities should be afforded on each floor These should open from rest rooms or from secluded halls It is an inexcusable blunder to locate toilets to open into corridors alongside of classrooms (12) In all school buildings where playgrounds are afforded ample toilet facilities must be placed in basements or detached buildings, and these made easily, but indirectly, accessible

The rural school buildings of our country are rarely furnished with even decent toilet facilities, not to mention sanitary matters No reform in sanitation in country life is more to be desired at this time than that connected with sanitary toilet systems Typhoid fever and hookworm disease, not to mention others, will never be eradicated until at every country school and every farmhouse sanitary toilets are available

**LAUD, WILLIAM** (1573-1645) — Archbishop of Canterbury and Chancellor of Oxford University After attending the free school in his native town, Reading, he proceeded to St John's College, Oxford, from which he graduated B.A. in 1589, M.A. in 1598, and D.D. in 1608. In 1611 he became president of his

college, a position which he retained until 1621. He held many preferments, and in 1633 became Archbishop of Canterbury. From 1630 to 1641 he was chancellor of the university. However reactionary Laud may have been in ecclesiastical and political matters, he exercised his position as head of the university to promote its welfare. He insisted on subscription of the three articles in the Thirty-sixth Canon by every candidate for a degree, on attendance at services and sermons, and on obedience to academic regulations, such as the wearing of academic dress, attendance at lectures, and taking examinations for degrees. Through his influence the use of Latin on all occasions was enforced. In 1628 on his inspiration a scheme was introduced for the appointment of proctors by each college in a certain cycle which eliminated the ever-recurring disputes. In 1636 were promulgated the Laudian or Caroline Statutes (*Corpus Statutorum*), which had been so carefully drafted under Laud's supervision that they remained practically until the University Reform Act was passed in 1854. While they destroyed the democratic control of university affairs, the Statutes introduced a good administrative system, at the head of which stood the Vice-Chancellor, appointed by the Chancellor and Convocation from among the heads of colleges. Public oral examinations for both the B.A. and M.A., based on a broad curriculum, were introduced and enforced, and superseded the obsolete disputations. Laud was a liberal benefactor of the university; he himself presented oriental MSS. and secured other literary gifts; he founded and endowed a chair in Arabic, and obtained for the university the privilege of printing Bibles. While his position warranted such action as he took in relation to Oxford, his proposal to visit Cambridge in 1636 to enforce Anglican discipline met with considerable opposition, and although his right as metropolitan was secured to him by royal decision, the threatened visitation never took place.

**LAURIE, SIMON SOMERVILLE** (1829–1909). — British educationalist, who held one of the first chairs in education established in Great Britain. In 1876 he was appointed first Professor of the Theory, History, and Practice of Education in the University of Edinburgh, and continued in office until his resignation in 1903. In 1882 an unsuccessful attempt was made to bring Laurie to Columbia University. His principal contributions to educational history and theory were *Primary Instruction in Relation to Education* (1867); *Life and Edu-*

*cational Writings of John Amos Comenius* (1881), *Medieval Education and the Rise and Constitution of Universities* (1886), *Language and Linguistic Method in the School* (1890), *Institutes of Education* (1892), *Historical Survey of Pre-Christian Education* (1900), *Studies in the History of Educational Opinion since the Renaissance* (1903). He is also well known as a writer on philosophy, his principal contributions in this department of knowledge being *Metaphysica, Nova et Vetusta* (1884), *Ethica, or the Ethics of Reason* (1885) and *Synthetica, being Meditations epistemological and ontological* (Gifford lectures of the University of Edinburgh, 1905–1906). Laurie's theory of education is contained in his *Institutes*, first published in 1892, and his conception of the aims and methods of education is largely determined by his philosophical standpoint, and is the practical application of his views on metaphysics and ethics. His philosophy was to a large extent determined by his study of Kant, and to a lesser degree by his reading of Fichte and Hegel. According to Laurie, we may distinguish within experience two grades of knowledge, a sentient experience or knowledge in which facts and events are connected merely by their time and space connections. This kind of experience is found in the life of animals, of the young child, and a very large part of the experience of many men is of this nature. On the other hand, we may have a rational knowledge or experience in which events and facts are connected by means of internal or intrinsic connections. Now man differs from the animals in that he is an active reason, and the whole upward progress of man may be considered as the process by which sentient experience is lifted up or converted into rational experience. Hence on the ethical side, the work of reason is to ascertain the meaning of impulse and to rationalize it, and as a consequence the supreme end of education is to endeavor "to build up" in the mind of the child and youth a system of moral ideas which will constitute a permanent reservoir of motives always ready for use, whether in moral judgment or moral action. For "man is an ethical being only so far as he is a self-regulated being." Similarly, on the intellectual side, method in education is the active will or reason gradually converting this merely given sentient experience into rational knowledge, or it is the passing from the mere particulars of sense to the universals of reason. Hence in education the all-important thing is the evoking of the will or reason to undertake the task of rationalizing the given sentient experience. The difficulties of such a conception of experience are similar to those met with in Kant's philosophy. If we assume at the beginning a dualism within experience, it is difficult to conceive how this can be finally overcome. Of his historical writings the most important is the account of *Pre-Christian Education*. A. D.

### LAUSANNE, THE UNIVERSITY OF. —

One of the oldest institutions of higher learning in Switzerland, having been established as an academy as early as 1536. Its origin is directly connected with the introduction of the Reformation in French Switzerland, the academy serving as a training school for Protestant clergymen. It was not until the beginning of the nineteenth century, however, that the academy was extended, the first step in this direction being the establishment of chairs of philosophy and law. A closer approximation to a real university was secured in 1838, when a reorganization of the institution resulted in the formation of four faculties, — theology, law, pure science, and letters. The technical school (founded in 1853) was added in 1869, and four years later a school of pharmacy, in 1888 an independent medical school was founded, which had existed for several years before this as a special division of the faculty of pure science. The institution was finally raised to the rank of a university in 1890, and consists at the present time of the faculties of Protestant theology, law, medicine (including dentistry), letters (including a special school for the teaching of modern French), and science. The last mentioned is divided into three groups (a) mathematics and natural sciences, (b) pharmacy, (c) engineering.

The language of instruction is French, but eight classes in the faculty of law are given in the German language, there being a fair number of German students at the university. The Cantonal Library contains about 285,000 books and pamphlets. In addition to the theological faculty of the university, there exists in Lausanne a divinity school of the Free Evangelical Church of the Canton of Vaud, established in 1847. Lausanne also possesses an academy of commerce. Both the latter and the university offer vacation courses during the summer months. Connected with the faculty of science is a special institute for agricultural chemistry, while with the faculty of medicine are affiliated a large and a smaller hospital, and a blind asylum with an ophthalmological clinic. In the summer semester of 1910 there were in attendance 1187 students, including 169 auditors, the matriculated students being distributed as follows: theology, 15, law, 267; medicine, 321; philosophy and science, 584. About one third of the students, including the majority of the auditors and almost half of the students in the medical school, are women, the percentage of matriculated women students

### LAVAL UNIVERSITY, MONTREAL, CANADA.

— A Catholic University established at the request of the Bishop of Montreal as a branch of the Laval University in Quebec. Faculties of theology and law were established in 1878, medicine in 1879; and arts in 1887, although the arts faculty has never been developed beyond the definite provision of courses in French. Instruction is in French, except in the faculty of theology, where Latin is used. Connected with the university are the following schools: École Polytechnique (1874); Comparative Medicine and Veterinary Science (1886), Dental Surgery (1894); Pharmacy (1906); Agricultural Institute (1893); Higher School for Young Women. The Montreal institution became wholly independent in the matter of administration in 1889, but the degrees are still conferred only by the Quebec institution. The enrollment of students is about 1000.

### LAVAL UNIVERSITY, QUEBEC, CANADA

— A Catholic university, founded by the Seminary of Quebec in 1852, when the royal charter was obtained. The institution was recognized by a Papal Bull in 1872. There are four faculties: theology, law, medicine, and arts, and schools of surveying and forestry. The Visitor of the university is the Archbishop of Quebec, who appoints the professors in the faculty of theology. The university is administered by a rector, vice-rector, and a council consisting of the directors of the seminary and three senior professors in each faculty. A number of seminaries and colleges are affiliated with the universities. The enrollment of students in 1910-1911 was 421.

### LAVATER, JOHANN KASPAR (1741-1801).

— This passionate and influential Swiss preacher and writer achieved his career in his native city, Zurich. As a Protestant he was a champion of religious liberty, but at the same time narrow in his own theology. Because of his strong enthusiasms and convictions, and of the mystical tendencies in his thinking, he was frequently subject to charges of heresy. He was known also because of the friendships he formed with Fichte, Goethe, Pestalozzi, and others. His lively human sympathy, his keen observations of human faces, and his skill as an artist in sketching them enabled him to produce the memorable work on physiognomy on which his fame rests. In 1775-1778 he published in four volumes the *Physiognomische Fragmente*

zur Beforderung der Menschenkenntniss und Menschenliebe, which has credited him with having founded the art of interpreting human character through expression, chiefly of the face. Without a knowledge of anatomy, he endeavored to frame a few principles to guide this art. The form of a human being is somehow significant of its inner nature. Character is expressed by movement. The mind's qualities are definitely and legibly expressed in the face. The book produced a great and lasting impression, although its scientific merit was limited. E F B

**LAW** — Generally speaking, a law is the statement of an order or relation among the elements of an object or situation, this order or relation being a means of understanding, organizing, and controlling other traits of the object or situation in question, and of reducing other situations or objects, apparently unlike, to a form in which the same, or a closely connected, method of treatment is applicable. A law is thus, logically speaking, a statement of a relation or order which is employed as an effective method of procedure in further dealings with phenomena.

The kind of order that is significant and the kind of procedure that is indicated depends, of course, upon the character of the material dealt with. The fundamental distinction of subject matter is that between acts (or functions) and states (or structures). As the primary human concern is the maintenance of life, and especially of group or associated life, the first type of law to emerge into conscious recognition was the rules of order applicable to the activities of human beings in relation to one another, — laws in the *jural* sense, whether political or moral. Now a statement of an order among *acts*, when employed as a determining method with respect to further acts, is obviously a *rule of action*. It presented itself, accordingly, as having authority over phenomena, as in some sense a *command* or *injunction* to act in certain ways. When attention was directed to natural existences, and the effort was made to discover and state a uniform order among them, the inevitable tendency was to conceive of natural law after the analogy of jural law, as a disclosure of a superior authority which "governed" the particulars which were then conceived after the manner of subjects "obeying" law. The course of the authority to govern was referred to God, Nature, Forces, or Reason, according to the tenets of a philosophical school.

In the eighteenth and nineteenth centuries, the advance of science produced the positivistic movement. According to this movement, a

law is simply a statement of an order of coexistence or sequence among phenomena (as the elements of a phenomenon). The conceptions of authority, of governing power and obedience were eliminated, being simply a formulation of uniformity abstracted from phenomena. This conception makes a complete break between jural and scientific law.

This distinction marked a most important advance in science and culture. Stated in this absolute form, it brought with it, however, its own peculiar difficulties. Jural and moral laws were conceived now only as a command, an imperative. Hence they seemed arbitrary, resting in ultimate analysis either upon mere superiority of force, or else upon purely ideal considerations of what should be, what *ought* to be, lacking positive, existential force and efficiency. In the first case, law meant despotism, in the second, an empty abstract conception of what ought to be, as over against what is. On the other hand, scientific and natural law, being conceived as merely a uniformity among things as they exist, was completely divorced from matters of action, save as action was reduced to the type of given physical existences — to the denial, accordingly, of its significant traits *as action*.

Various tendencies have converged to bring forward a third conception of law, which brings the practical and the scientific senses of the term into working relations with each other, eliminating, however, the sense of superior authority and of coercive command. What makes in any given case a statement of an order (whether physical or social) a law is its *use as a method of procedure* in dealing with further cases, with future possibilities. A scientific law is thus not a mere statement of coexistence, it is such a statement employed as a method of procedure in further inquiries, interpretations, and organizations. It is thus in some sense a rule of action, that is, a way of directing or guiding action in the region of investigation. Moreover, the statement of a uniform order is either limited to the particular cases in which it has been already observed, or else in its extension to new cases is hypothetical — a rule of anticipation, prediction, and probable behavior. In addition, through applied science and the arts such uniformities as are observed and abstracted are embodied in methods of controlling and adapting things to human needs, and thus pass into the realm of overt and social action.

From the side of social and moral concerns, a converse movement has taken place. With the development of democracy and freer intercourse, moral and political laws lose alike the form of rigid imperatives and of empty ideals, and tend to be conceived as a conception of an order of action adapted to securing ends of objective value. From both sides, accordingly, the sharp antithesis between a law of natural existence and one of practical endeavor is

softened down, so that both intellectual and practical elements are included in the concept of law.

### **LAW, EDUCATION FOR THE. — Historic and Sociological Position of Law** —

Law shares with divinity the distinction of being the first of academic studies. The earliest university was the temple school, in which the divine law, which included the human, was inculcated, and in which the priest, who was also the lawyer, was trained for his sacred calling. Not through all its history, not through the long process of its secularization, not through all its vicissitudes of contempt and esteem, has the law ever quite lost its ancient distinction of a quasi-sacred doctrine to be seriously and reverently studied. Other professional studies, like that of medicine, have arisen, as a necessity of professional development, through the decay of the system of apprenticeship through which admittance to the guarded privileges of the profession was gained. Wherever legal education betrays this tendency, as it has in England, and, indeed, in all common law countries, the result has been due to special conditions, — in England, to a peculiar and distinctive legal development, isolated from the main currents of European thought, in America, to the exigencies of a forced legal development under primitive conditions.

But these facts, which loom large to the student of English and American conditions, must not be permitted to distort his view, of the general and permanent position of law in the scheme of higher education. Considered merely from the historical point of view, the loss of its sacred or religious character may, indeed, affect its prestige, and might conceivably relegate it to a subordinate place in the university curriculum, or even eliminate it entirely therefrom. But with the decay of the conception of law as a branch of divine science there has arisen a recognition of its controlling position among the social sciences. As the concrete expression of the aggregate of social forces which dominate the world and shape its development, it can no more be separated from other social sciences than can the will of man be isolated from the intellectual and moral qualities which set that will in motion and direct its activities. Robbed of all its attributes of divinity, law remains as the will of society expressed in action, and as such its place in the hierarchy of learning is secure.

That law has not as a university discipline suffered an eclipse during this period of transition from the old to the newer conception of its place in the divine human order is due to the fact that the transformation of opinion has been a gradual, almost an imperceptible

one, the modern view coexisting with and gradually supplanting the older, a process which is still incomplete. If the great schools of law which flourished at Pavia, Ravenna, and Bologna in the twelfth and thirteenth centuries have lost their honorable preeminence, the fact is due to no failure of appreciation or of service, but only to the fact that newer foundations more richly endowed or more favorably situated have exercised a more powerful attraction on the aspiring votaries of the science. The 12,000 students enrolled under the law faculties of the German universities in the winter semester of 1911-1912 furnish convincing evidence of the permanence and importance of the law as an academic discipline. (For the history of legal education on the Continent see UNIVERSITIES for its history in England, see INNS OF COURT.)

**United States.** — *Place of Law in American Traditions* — In no community of ancient or modern times has the study of the law been more general or pursued with greater avidity than in the United States. The legal character of the controversies of the American colonies with the mother country drew many of the more ardent patriots of the day to the study and practice of that profession, and gave it unexampled scope and influence. Edmund Burke, in a notable passage, attributed the spirit of resistance to aggression which the colonists displayed to their familiarity with the principles of English law. The "government of laws, not of men," which arose on the ruins of the colonial system, the institution of a federal system based on a constitutional document of a highly legal character, the assumption by the courts of the function of determining the constitutional validity of acts of legislation, all conspired to give to the lawyer and the study of law a high degree of political importance. The result has been not only to enlarge to an unprecedented degree, perhaps to exaggerate, the function of the law as an instrument of social regulation, but to attract to the profession multitudes of young men whose interest lay rather in the political than in the legal sphere of activity.

For nearly a hundred years after the settlements in New England there was no recognized law, no settled procedure, and consequently no need of lawyers. The judges were for the most part laymen, and they decided the causes brought before them on principles of "natural justice," or, in Massachusetts and Connecticut, in accordance with the "Word of God." The first code of laws of the Commonwealth of Massachusetts, prepared under authority of the General Court, or Legislature, was drawn by the Rev. John Cotton, and entitled *A Copy of Moses, his judicials, compiled in an exact method*. There were no English law books in the colonies until the Governor of the Massachusetts Bay Colony, in 1647, imported two copies of *Coke on Littleton* and half a

dozen other volumes "to the end that we may have better light for making and proceeding about laws." It was more than a hundred years later that the first volume of law reports in America appeared (Kirby's *Connecticut Reports*, published in 1789), and not until 1802 that the first book of practice (*American Precedents of Declarations*) issued from the press.

*Education in the Law during the Colonial Period.*—Under these novel conditions—a new body of law slowly taking shape in the customs of an isolated community, a bench composed of ministers, business men, and "gentlemen" having no legal training or experience, with no reported decisions and no indigenous legal literature—it is not to be wondered at that a trained bar was long in appearing. Attorneys there were in plenty in all the colonies, but these were for the most part men of no education and of little character. The first lawyers to appear in the colonial courts were derelicts of the profession in England, and, toward the latter part of the seventeenth century, an occasional barrister of reputation whom fate had exiled from the atmosphere of the Inns of Court. Then early in the new century young Americans of good family began in increasing numbers to resort to London for an experience of Old World life, and not a few of them took advantage of the opportunities there afforded to pursue the study of law. It is significant of the spirit of the time, in England as well as in the colonies, that many of these had no professional aim, and that the law presented itself to them as a branch of polite learning suitable for gentlemen who might reasonably expect to play a prominent part in the public or social life of the time. The instruction afforded in the time-honored universities of the common law, the Inns of Court, was of an insignificant character, but the courts of law and chancery, presided over by such men as Mansfield, Kenyon, Ellenborough, Thurlow, and Eldon, and illuminated by the eloquence of Erskine, Pitt, and Camden, were then real schools and to these they resorted. There, too, were the priceless books of the law and the expanding treasures of the law reports, and these they read with an eager interest which, in this more sophisticated and heavy-laden age, we cannot easily understand. It is said that something like twoscore American-born lawyers were educated in England prior to 1760, and that 115 more were admitted to the Inns of Court (*q.v.*) between that date and the close of the Revolution—more than two thirds of them from the southern colonies.

Apart from private reading of the few accessible English books and the practice of attending court, two courses offering a more systematic training were open to the law student of the revolutionary period. He might secure a position as copyist or assistant in the clerk's office of some inferior or higher court, or, if he had the means, he might enter the office of

some leading member of the bar, preferably one of the few who had good law libraries, "there absorbing, by study, observation, and, occasionally, by direct teaching from his senior, the principles of the law" (Warren, *History of the American Bar*). The latter was a method open only to young men of means, as the privilege of entering the office of a lawyer of reputation could be gained only by the payment of a considerable fee. A promissory note of George Washington is still extant, undertaking "to pay James Wilson, Esq., on order on demand one hundred guineas, his fee for receiving my nephew Bushrod Washington as a student of law in his office." The memoirs of the time show that as a method of legal instruction this system left much to be desired. The lawyer was too apt to regard the fee as compensation for entering the office and for the privilege of reading the law books or the notes and briefs of the office, and not as calling for any personal instruction or advice. In some cases, it is true, the arrangement took on the form of a free apprenticeship, the incumbent being privileged to aid in the preparation of cases and less frequently to assist in their trial. But the system must in all but the exceptional cases have been an unsatisfactory one, and the lawyer gained his education in legal principles after rather than before his admission to the bar. Indeed, even under the most favorable circumstances the education of the student must have been of the most meager character. After all, the books available were few in number, and until the appearance of Blackstone's work in 1769, were all of a highly technical character. Littleton's *Tenures* and Coke's learned but crabbed and unsystematic *Commentaries on Littleton* were the works generally recommended, and to most students they must have proved an obstacle rather than an aid to the mastery of the law. Their artificial, limited, and fragmentary character, as well as their remoteness from the actual conditions and the actual law of the colonies, rendered them peculiarly unsuitable for the use of students. To these must be added one or two books on the technical system of common law pleading of the day and, perhaps, a digest or abridgment of precedents. There was nothing in all this to give a comprehensive view of the law or to enable one to grasp it as a system or to relate it to the social life of the time. A few of the more favored students were more fortunate in the range and variety of their studies. John Adams records that he read the *Institutes of Justinian*, besides other works on Roman Law, and Chancellor Kent added to these the study of Grotius and Puffendorf, Rapin's *Dissertations on the Laws and Customs of the Anglo-Saxons*, and Sir Matthew Hale's *History of the Common Law*. Daniel Webster's reading included all the standard English books, and, in addition, the works of Vattel, Burlamaqui, and Montes-

quieu But these were the exceptional men, in talent as well as in opportunity, and though, through their professional eminence, they exerted a marked influence on the course of legal development, they could do little to affect the general standard of legal education

It is a curious and interesting result of this wide diversity of training and equipment of the lawyers of the formative period in our legal development that both groups—the half educated through their defective grounding in the principles of the common law, the highly educated through their familiarity with the writings of continental jurists of the philosophical sort—contributed to maintain for a considerable time the freedom and flexibility of American law It was not until the bar generally as the result of a more thorough training in the common law had become indoctrinated with the spirit as well as the rules of that system, that our jurisprudence became, like that of the mother country, authoritative and inflexible In the meantime the restricted and technical character of the education of the greater part of the bar had produced the unfortunate effect of imparting to our law a certain hard and technical character which it has never lost Littleton and Coke and Hawkins (*Pleas of the Crown*) and Lilly (*Entries and Doctrina Placitanda*) were not the most desirable teachers for a new society of freemen with a new world to create And we may safely charge to their influence the feudal survivals and the rigid and artificial legal reasoning which have done so much to hamper the free development of life in the western world

*The Influence of Blackstone* — Two events of capital importance in the history of legal education in America marked the latter part of the eighteenth century the appearance of Blackstone's *Commentaries on the Laws of England* and the institution of systematic legal instruction in colleges and schools of law That these two events were not unrelated will appear in the sequel It would be difficult to exaggerate the influence of Blackstone's work on the bar or on the course of legal development in this country Its success was instantaneous, and it became at once the favorite, if not the only, textbook of the American student Two years after the publication of the fourth and concluding volume of the work in England it was republished in Philadelphia, and it is said that 2500 copies of the work were immediately absorbed in the colonies before the outbreak of the Revolution Burke, in a speech delivered in 1775, to which reference has already been made, ventured the assertion that nearly as many copies of the *Commentaries* had been sold in the colonies as in England The reasons for this success are not far to seek The book made a varied appeal—to the sentiments as well as to the needs of the American student. Its panegyrics of Anglo-Saxon liberty and its

denunciations of Norman and Stuart tyranny, however turgid and unconvincing they may seem to the reader of a later date, awakened a responsive chord in the men of that time of revolt That the common law, instead of being the convenient instrument of despotism, was in spirit and in truth the guardian of the ancient liberties of the race, was a welcome revelation to the lay community as well as to the bar, while the legal profession acquired a new dignity as the inheritors of such a tradition, the appointed guardians of its sacred flame The utilitarian merits of the work, as a trustworthy guide to a knowledge of the law, were not less conspicuous Though necessarily somewhat superficial, it was upon the whole an accurate presentation of the common law and equity systems as administered in Westminster Hall Over Coke and Littleton it had the advantage of being modern, untechnical, and readable Its somewhat florid and balanced style did not repel the reader of the time of Gibbon and Burke, and even to-day it can, like them, be read with pleasure as well as profit But the chief merit of the work, and that which gave it instant and complete command of the field of legal education was its comprehensiveness and its systematic character In its pages it was possible for the first time to see the English law as a whole, and, what is more important, as a connected whole, related in all its parts and inspired by a common spirit The law now had unity, reason, a soul, and Blackstone was its prophet But a prophet is more than a teacher, he is also an authority, and so it came to pass that the new book of the law was received not only as an indispensable means of acquiring a knowledge of the law, but as the final and authoritative statement of its rules and principles But in the course of time its inspiration came to be questioned Professor William G. Hammond, perhaps the most learned of the American commentators on Blackstone, tells us in the preface to his edition of the *Commentaries* (published in 1890) that "upon all questions of private law, at least, this work stood for the law itself throughout the country, and at least for a generation to come exercised an influence upon the jurisprudence of the new nation which no other work has since enjoyed and to which no other work can possibly now attain "

But it is rather with his position as a teacher and with the indirect influence which he exerted on the development of the law as the result of forming the mind of the American bar, that we are now concerned, and here his authority was more enduring A knowledge of Blackstone was everywhere accepted as sufficient evidence of fitness for the bar The first effect of this was to set the law student free from the necessity of seeking a master or an office connection There could be no need of a teacher or a library for one who had the entire body of the law

within the compass of a single book, and that a readable, understandable book. It was, perhaps, to be expected that the law school, when it came, would put the *Commentaries* in its proper place, as only one of many books of the law which the student must master, but the contrary was the case. Blackstone may almost be said to have been the father of the American law school. He made it possible, and supplied it with the principal material for instruction. As an illustration of the place actually occupied by the work in the teaching of the schools it is interesting to note that a manuscript volume of the lectures delivered at the famous Litchfield Law School in Connecticut shows numerous citations of authority, but that "the references to Blackstone not only outnumber those to any other book, but may be safely said to outnumber all the rest together."

It is, of course, obvious that the swelling tide of legal literature during the past century, and, still more, the enormous expansion of the law in that period, must have seriously affected the position of Blackstone's work as the principal source of legal knowledge. Law students can no longer satisfy the demands of the bar by the easy process of reading that now venerable classic. But it is certainly no exaggeration to say that by far the greater number of the lawyers now living in this country read the *Commentaries* as an important, if not essential, part of their education for the bar, that in most cases it was the first law book placed in their hands, and that their examination for admission was, at least in part, based on it. It still forms a part of the regular work of instruction in perhaps a majority of the law schools, and is an important part of the recommended reading in nearly all of them, while, of the multitude of young men and women who still come to the bar without a law school training, it is safe to say that three fourths or more read Blackstone in whole or in part. In closing our account with the greatest single influence on education in the western world, let it be noted that we owe to it more than can be estimated in the establishment of a tradition of the unity of the law and a resultant general uniformity and consistency in the law of the several states of the American commonwealth — a priceless boon, inasmuch as it has made for national unity and social solidarity. How much of the eighteenth century that still cumbered the law of the twentieth we also owe to it, it would be vain to inquire. The fault, if fault there be, is due not to Blackstone, but to the undue persistence of the Blackstonean tradition, and for this our law schools are to blame.

*Early Law Schools in America* — It is a disappointment to discover that legal education does not enter upon a new phase with the advent of the law school. Originating as it did, it was of course devoid of any academic

tradition. The great European schools of jurisprudence had scarcely a name in America. The civil law was an alien, and, to the average lawyer, an abhorrent system, bound up in some mysterious way with popery and the imperialistic system of the Continent. It is true that sporadic efforts were made in some of the colleges (at King's College in New York, now Columbia University, in 1773, at the College of William and Mary in Virginia in 1779, at Yale College in Connecticut in 1789, and at the College of New Jersey, now Princeton University, in 1795) to maintain courses of lectures in the law of nature, international law, and the civil law, but these were feeble beginnings, born out of time, and came to nothing. The systematic teaching of the law was to come from the profession, not from the universities, and was to be born of the failure of the apprenticeship system, not of the scientific or historical spirit. Indeed, it could not be otherwise. As has elsewhere been said, academic instruction presupposes a body of organized knowledge, and that was lacking in the law of the period with which we are dealing. There was as yet no system — not even a coherent body — of American law. The common law, then and now a half foreign thing, had indeed grown to be a well articulated, developed system of law, but it had never been rationalized, systematized, and related to other legal systems or to ethics and the social sciences. There was an English law, but no English jurisprudence. Accordingly, neither in England nor in this country was it possible to teach the law of the land philosophically or systematically. The result was that, as soon as the instructor undertook to teach the law as a connected whole, he found himself teaching a single book — Blackstone's *Commentaries*. Now, no system of academic instruction can be based on a single book, however epoch-making. Even the sacred books of the race had to be developed by glossators into a literature before they became fitted for this purpose.

Perhaps the most interesting attempt to make the law a subject of academic instruction at this period was made at Columbia College. As early as 1784 the trustees of the college voted to establish a law school with three professorships, viz. "A professorship in the Law of Nature and Nations, a professorship in the Roman Civil Law, a professorship in the Municipal Law." Lack of means prevented the carrying out of this ambitious project, but in 1793 it was found possible to make a beginning, and James Kent was appointed to the first regular law professorship. This brilliant young man, then at the threshold of his long and distinguished career, took up his duties with energy and in a true scholarly and scientific spirit. His was a noble aim, but was not destined to be realized. In his first course, given in the fall of 1794, he "was honored," he notes, "by the attendance throughout the

course of seven students and thirty-six gentlemen, chiefly lawyers and law students, who did not belong to the college." The next year he gave a more extended course to two students and his own clerk. No students presenting themselves for the third year, he tendered his resignation, which was accepted in April, 1793. In 1823, after twenty-five years of distinguished public service as judge, chief justice and chancellor of the state of New York, he resumed his chair at Columbia, which had in the meantime remained unoccupied. The fame which he brought back with him and the growing importance of New York as a legal center drew to his lectures more students than had been attracted to his previous venture, but he soon wearied of the unaccustomed labor, and, after three years of service, again resigned his chair. But the service of these years was not confined to the influence that the lecturer exerted on the few students who came under his immediate instruction, for they resulted in the production of the first systematic treatise on American law and one which was destined to hold that distinguished place to the end of the century. It was in 1826 and 1827 that Kent embodied in printed form the lectures which he had delivered during his second incumbency of the professorship in Columbia College under the title *Commentaries on American Law*. While this work of the American jurist did not take the legal profession by storm, as that of the great English commentator had done, and while it never took the place of the latter as the favorite textbook for students, it had, nevertheless, an instantaneous and permanent success. Though less systematic and less comprehensive than Blackstone's work, it was at once accepted as a clear, learned, and accurate exposition of the law of the land. As the only work which purported to cover the field of American law, it became the indispensable adjunct of the English work, and its graceful style commended it to the lay reader as well as to the legal profession. The permanence of its influence may be gauged from the fact that it has passed through fourteen editions (the last published in 1896), and that it is still deemed a necessary part of every well equipped law library and is still frequently cited in the courts throughout the nation. It is significant of the rapid growth of a consistent native jurisprudence under the influences above described that, by the end of the first quarter of the century, only forty years after the Revolution, a treatise on American law of a fairly comprehensive and systematic character should have become possible. The foundations of an American legal education were beginning to appear—a consistent body of national law and a legal literature.

The first of the schools which were destined to become the characteristic note of American legal education was founded in 1784 at Litchfield, Conn., by Tapping Reeve, a learned

lawyer, who afterwards became Chief Justice of the Superior Court of Connecticut. It had a brilliant career of thirty-five years, in the course of which it educated over a thousand young men for the bar and carried on its rolls the names of many men who afterwards became famous in political and professional life. Its influence may be measured by the fact that it drew its students from all parts of the country from Maine to Ohio. President Timothy Dwight of Yale College gives a favorable view of the character of the instruction imparted in the school, saying, "Law is here taught as a science, and not merely nor principally as a mechanical business; not as a collection of loose, independent fragments, but as a regular, well-compacted system." This was written in or about 1820, when the school numbered 40 students and was at the height of its influence. It was probably to the rapid rise of the Harvard Law School after 1830 that the decay of the Litchfield school was due. The New England of that day was incapable of supporting more than a single flourishing school of law. The Harvard School, founded in 1817, led a precarious existence until the establishment of the Dane Professorship in 1830. Thus rendered it possible to secure the services of Joseph Story, then a justice of the United States Supreme Court, whose fame, with that of his distinguished colleagues, John Hooker Ashmun and Simon Greenleaf, attracted students from all parts of the country, and soon made the Harvard institution the leading law school in the United States. In the meantime several other schools of temporary fame and of varying influence, perhaps a dozen in all, had come into existence and passed away. These were all small, and made little or no mark on their time. One of the most famous of these, founded by Judge Samuel Howe at Northampton, Mass., is recorded as having "flourished from 1823 to 1829, with a yearly average attendance of ten students." Well might the learned David Hoffman of Maryland say of this period, "In America alone a law student was left to his own insulated and unassisted efforts." The comment of the author of *A History of the American Bar*, that "the legal profession had not yet fully accepted the idea that law could be learned in a law school as well as in a law office" was to hold good for a long time to come.

The character of the instruction given in the schools of this period varied only with the genius and temperament of the instructor. So far as the scanty records of the time show, the methods employed were much the same in all. Generally Blackstone's *Commentaries* was placed in the hands of the students and furnished the basis of instruction in the law as the "regular, well-compacted system" described by President Dwight. This was supplemented by courses of formal lectures

on the several branches of the law as administered in the United States, by weekly or more frequent "quizzes" on Blackstone and on the lectures previously given, and by "moot courts," usually conducted by the instructors. In some instances, as at Litchfield, the whole ground, including the substance of Blackstone, was covered in lectures, which the students were expected to commit to writing. St. George Tucker, an eminent lawyer of Virginia, made his lectures on Blackstone, delivered at William and Mary College, the basis of a well-known edition of the *Commentaries*, published in 1803. The instruction in all of the schools was of a strictly professional and utilitarian character, confined to the law which the student might expect to encounter in his subsequent practice, and included no legal history, general jurisprudence, or civil law. Occasionally international law found a place in the curriculum, and the momentous constitutional decisions of the time were commented on and discussed. Such was the American law school of the period of national expansion, and such it continued to be, in method and in spirit, almost to the end of the century.

*The Nineteenth Century Law School Development.*—But the law school movement was now on. Between 1830 and 1860 numberless schools of the general character of those described above sprang into existence, many of which proved to be permanent. Among these were several of the university foundations which have since become deservedly famous, such as the Law School of Yale College in New Haven, established in 1843, that of the University of Pennsylvania at Philadelphia, in 1852, of the University of Michigan at Ann Arbor in 1859, and, in the same year, the Union College of Law of Chicago, which later became the Law School of Northwestern University and the Columbia Law School in the City of New York. There are no statistics available for this period, but the *Report of the Commissioner of Education for 1871* lists forty law schools as in existence at that date, with a total enrollment of 1722 students. As only one of these was without a university connection, it is obvious that the record is incomplete. There must have been a considerable number of private schools of the type of the Albany Law School (founded in 1851), maintained to satisfy a local need, which failed to attract the notice of the Bureau of Education. This is, perhaps, the explanation of the fact that no law schools are reported for seventeen of the thirty-seven states which then comprised the Union. The number of students was usually small, eight schools having less than a dozen each, and fourteen having twenty-five or less. Only four of the total number had more than 100 students in attendance, the Michigan Law School, which had already assumed the preeminence which it was long to retain in the West, leading with 321

But the movement for systematic instruction in the law had not yet gained the momentum which it was soon to acquire. During the decade from 1870 to 1880 only seven new law schools are reported, though the number of students had risen to 3227. By 1890 the number of schools had increased to fifty-four, with 5252 students. There were now eighteen schools with an attendance of 100 and upwards, the Columbia Law School leading with 625 students and Michigan a good second with 587. The Harvard Law School, which, under the administration of Professor C. C. Langdell, had already entered upon the career which was to make her for a generation the undisputed leader in legal education, had at that time 279 students enrolled. But the period of expansion had now come. The increasing volume and complexity of the law combined with the new and more exacting demands of the profession to demonstrate the inadequacy of the apprenticeship system, if such it can be called, and students flocked in increasing numbers to the existing law schools and demanded new ones. In the decade from 1890 to 1900 the number of law schools nearly doubled (there were now 100), and the number of students increased 160 per cent.

The demand for new centers of legal instruction must have been pretty well satisfied for the time being by the multiplication of schools in the last decade of the century, as only fourteen new law schools have since come into existence. But the swarm of students continues. The 13,642 of 1900 had in 1910 become 19,567, an increase of nearly 50 per cent. The growth in influence of the leading schools is attested by the fact that no less than sixty-five have to-day over 100 students each, that thirty-eight have an enrollment of over 200 each, eighteen of 300 and upwards, and ten of more than 400. The latest available reports give the Michigan Law School a student body of 897, Harvard of 810, the New York Law School of 763, the New York University of 688, and Columbia of 465. Two thousand students are enrolled in the law schools of Chicago, and 2500 in those of New York City.

Impressive as these figures are, it would be easy to exaggerate their significance. They do not indicate that the American lawyer has even yet fully accepted the idea that the law school is a better place than the law office for acquiring a knowledge of the principles of the law, but only that that idea is making its way in the profession. It is safe to say that even to-day not less than two thirds of those who apply for admission to the bar have gained their professional training wholly or mainly in law offices. Nowhere in the United States is attendance at a law school a prerequisite to admission to the bar. The tradition that law, being an art and not a science (for so the tradition runs), can best be acquired in the legal workshop survives with the notion that every

free American, who is a male of full age and not yet convicted of crime, is entitled to make his living by practicing law as well as in any other art or craft. Both these traditions have still enough of vitality in them to hamper the course of legal education, but both are slowly yielding to the pressure of the time.

The same conditions which were driving law students in increasing numbers into the law schools conspired to make the schools more exacting in their demands upon the students who resorted to them. These demands took on two forms — the requirement of a better general education and the raising of the standards of instruction. Down to the middle of the last century students were generally admitted to the schools without examination and without any close scrutiny of their qualifications for the study of the law. The first announcement of the Columbia Law School, published in 1859, provides that "Any person of good moral character whether a graduate of a college or not, may be admitted to either of the classes. No examination and no particular course of previous study is required for admission." It was not until 1876 that the additional requirement was made that the candidate "must be at least eighteen years of age and have received a good academic education, including such a knowledge of the Latin language as is required for admission to the Freshman Class of this College" — a standard which has now come to be general in the law schools of the country. Two influences, emanating from the profession have contributed to this result — persistent pressure from the American Bar Association (which, at its creation in 1878 had provided for a Committee on Legal Education) and the general adoption by the courts of rules for admission to the bar prescribing a minimum of previous academic training for all candidates. Probably the demand of the legal profession on the law schools would have gone no further had it not been for an impulse communicated by the universities.

It is significant of the movement of higher education in America that the law schools have almost from the beginning been university foundations. Of the 114 schools reported for the year 1910, only 20 are without a university connection. It is true that the relationship is in many instances only nominal, but even in such cases it tends to become real. Though for reasons elsewhere given the influence of the university spirit upon the law department has been slow in asserting itself, it is making itself felt in increasing measure. It is from this source that there has come a persistent and wide-felt pressure for a better preliminary education for law students. Harvard led off in 1897 by instituting the requirement of a college degree for admission to the law school of the university. Columbia followed with the same requirement six years later, but has since modified it in favor of a

three years' college course. The movement has gone on steadily, and is still in progress. While Harvard is still alone in requiring a college degree, at least six law schools now require three years, ten or twelve require two years, and a dozen or fifteen one year of college study as a prerequisite to admission.

Coincidentally with this development there has been a marked increase in the length of the law school course. The earlier schools seldom gave more than a year's instruction, but by the year 1880 thirty eight of the forty eight schools then in existence reported a two years' course. Of the 114 schools reported in 1910, only two confess to a course of one year, thirty four having a course of two years and seventy eight of three years. One of the most powerful influences in bringing about this rapid development of the law school course from two years to three was the Association of American Law Schools, organized by a group of representatives of the leading schools of the country in 1900, which after the year 1908 restricted membership in the Association to schools having a course of not less than three years leading to the first professional degree.

But the circumstance that has contributed most powerfully to the lengthening of the law school course, and one which is still operating, has been the general introduction into the schools of new methods of instruction involving a large increase in the time required to cover the ordinary subjects of the legal curriculum. Doubtless the "case system" of legal instruction would have come sooner or later in any event (it is at least as old as the common law), but its introduction at the critical period of legal education in America, which has been described above, was due to the genius of Professor C. C. Langdell of Harvard, who introduced it as the basis of instruction in that school when he assumed the position of dean in 1870. Based on the sound assumption that a system of law which has been developed by reported judicial decisions can best be studied in and through those decisions rather than in the writings of commentators and editors, the new method soon became a leaven which was in a short time to leaven the whole lump of legal education in this country. Properly employed, it became a powerful means of stimulating the interest of the student, and to the admirable use made of it at Harvard is to be attributed the second rise to greatness of that venerable seat of legal learning. Harvard found her first disciple in the Albany Law School, which adopted the "case system" in 1889, and in 1890 it was introduced in the Columbia Law School. Its progress since that date has been rapid, and it is now employed in a considerable majority of the law schools of the country.

The material equipment of the law schools has kept pace with their growth in size and in the intellectual graces. Most of them have separate buildings devoted to their use, and,

though some are still sadly deficient in library facilities, many of them have large and rapidly growing collections of law books. Twenty only are without libraries of their own, though these usually have access to the collections of state or county libraries. Thirty two more have less than 2000 volumes, but forty have libraries of 5000 and upwards, twenty four of more than 10,000, ten of more than 20,000, and eight of more than 30,000. The Harvard Law Library, one of the most complete in the world, contains 125,000 volumes.

It is in the persistently professional character of the law school that we find the chief source of its strength and of its weakness. Created by the profession and, for the most part, even in the university schools, controlled by it, it has kept in close touch with the administration of the law, and has thus been preserved from assuming too much of an academic character. The instruction, still for the most part given by lawyers in active practice, has been of the most concrete, practical character. In many of the schools the hours of instruction are still arranged with a view to permitting the students to carry on their work in law offices at the same time, and it is safe to say that a majority of the students in the law schools avail themselves of the opportunity so to do. This practice has not only militated against the influence of the law school as a seat of legal learning, but has put a premium on methods of instruction which made the least possible demand on the time and energy of the student. Even in schools in which this practice does not obtain, the professional influence has generally been thrown against legal studies of a general or "theoretical" character and against methods involving research. The result is that even to-day the curriculum of the law school seldom includes any subjects except those required for the bar examinations, and these comprehend nothing but those branches of the law which the lawyer is apt to require in his daily practice. Consequently few of the schools have deemed it necessary or proper to offer courses in the civil law, in legal history (even in the history of our own legal system), in general jurisprudence, or even in public law, other than the law of the federal constitution. Even when they are given, such studies are usually regarded as "frills" or "extras," and are apt to be relegated to an additional, postgraduate course which is rarely taken. A few schools, like those of Columbia, Northwestern, and now, perhaps, Harvard, must be excepted from this condemnation, a liberalizing influence, coming from a school of political science or a department of history or economics, having to a degree leavened the professional tradition in those institutions. The statement of the Committee on Legal Education of the American Bar Association contained in its Report of 1892 is as true of conditions to-day as it was of those

twenty years ago. "It is evident that the course of study in the schools is, with a very few exceptions, confined to the branches of practical private law which a student finds of use in the first years of his practice. It is the technical rather than the scientific or philosophic view of law which is taught."

**England** -- In England the house of the law has always been divided against itself. Even yet there is no promise there of that fusion of theory and practice, of academic with technical training, which the universities, through their control of professional education, are promising us in America. We may or we may not believe that the celebrated Lombard jurist Vacarius taught at Oxford in the middle of the twelfth century (the evidence is far from convincing), but certain it is that the study of that Romanized Roman law, which we call the canon law, flourished at both Oxford and Cambridge from an early period until prohibited by Henry VIII, and that the study of the civil law, of almost equal antiquity, was by the same monarch encouraged by the foundation of professorships at both universities. At the time when the Roman law was sweeping everything before it on the Continent, its study was pursued with enthusiasm in England, and there were not wanting those who anticipated a similar triumph for it over the barbarous English law. But the common law was a self-made, independent old body, with a way of its own. The creation of lawyers, who saw nothing good in anything of foreign origin and nothing but evil in anything Roman, it was intrenched in the Inns of Court (*q.v.*), where the members of the bar and their students lived and studied and disputed over the cases in the Year Books together. Thus in England, as later in America, legal education was the work of the active bar, and it is to this fact that Maitland (*English Law and the Renaissance*) attributed that "toughness" of the common law which enabled it to resist and defeat the Romanizing influences emanating from the universities. From that day to this the two streams of legal learning have flowed on without mingling -- from the universities, the stream of legal science, philosophy, and history, from the Inns of Court, the stream of practical training which should fit men for the actual work of the bar. Sir John Fortescue, Chief Justice of the King's Bench in the reign of Henry VI, in his treatise *De Laudibus Legum Angliæ*, raises the question "Why the laws of England, being so good, so fruitful and so commodious, are not taught at the universities, as the Civil and Canon Lawes are," and he answers it, not very convincingly, by saying, "In the universities of England sciences are not taught but in the Latin tongue; and the lawes of the land are to be learned in three several tongues to witte, in the English tongue, the French tongue and the Latin tongue. . . . Where-

fore, while the lawes of England are learned in these three tongues, they cannot conveniently be studied in the universities where only the Latin tongue is exercised" Doubtless the real reason is to be found in the learned Chief Justice's further statement that "the same Lawes are taught and learned, in a certaine place of publique or common studie, more convenient and apt for attayning of them than any other University For this place of studie is situate ne to the King's Courts, where the same lawes are pleaded and argued and judgments by the same given by Judges, men of gravitie, ancient in years, perfit and graduate in the same lawes Wherefore, every day in Court, the students in those Lawes resort by great numbers into those Courts wherein the same lawes are read and taught as it were in common scholes"

The reference is to the Inns of Chancery and the more famous Inns of Court, which together constituted at that period "as it were an university or school of all commendable qualities requisite for noblemen," the charges being so high that "the children onely of Noble men doe studie the Lawes in those Inns" A later writer, Joseph Walton, Esq., Q C in a paper read before the American Bar Association in 1899, speaking of the great activity of corporate life which the Inns displayed during the sixteenth and early seventeenth centuries, says, "The education of the students was not left in the hands of salaried teachers, but the Benchers (the governing body of the Inns) and the Bar alike cooperated in the work" The fact that then as now no man could practice at the English bar unless he had been admitted as a student at one of the Inns of Court and had been in residence the prescribed number of terms furnishes the final and convincing answer to the question propounded by Sir John Fortescue.

But the Inns were to fall upon evil days. As we have learned in America, instruction by "salaried teachers" has some advantages over that imparted by busy members of the profession, and so it came to pass that the bar, which had created the system of legal education, through neglect destroyed its own offspring By 1688 it was possible for Roger North to say. "Of all the professions in the world, that pretend to book learning, none is so destitute of institution as that of the Common Law Academick studies, which take in that of the civil law, have tutors and professors to aid them, and the students are entertained in colleges under a discipline, in the midst of societies, that are, or should be, devoted to study, which encourages, as well as demonstrates, such methods in general as everyone may easily apply to his own particular use. But for the Common Law, however, there are societies which have the outward show or pretense of Collegiate Institution, yet in reality nothing of that sort is now to

be found in them; and whereas in more ancient times there were exercises used in the Hall, they were more for probation than for institution, now even those are shrunk into mere form, and that preserved only for conformity to rules, that gentlemen by tale of appearances in exercises rather than by any sort of performances, might be entitled to be called to the Bar"

After the abdication of its teaching function the corporate bar left the students to their own devices The "lawes of England" were not taught in the universities, and thus the system of an office apprenticeship grew up, the student becoming a pupil for two or three years in the chambers of a conveyancer, equity draftsman, or special pleader The requirement of twelve terms (three years) of residence in the Inns of Court was satisfied by the eating of a certain number of dinners in the Hall This was the state of legal education in England from the middle of the seventeenth to nearly the middle of the nineteenth century, when (in 1832) the great Society of Attorneys and Solicitors was formed, for the purpose, among other things, of providing for the education of its branch of the profession, and when (in 1840) the Benchers of the four Inns of Court established the Council of Legal Education

The modern period of legal education in England coincides pretty nearly with what may be called the second period in the development of the law school in the United States, dating from about the year 1860 There, as here, it was due not to an awakening of the universities to a sense of their duty to the community, but to a conscious effort of the profession to secure a better equipment for the discharge of its increasing responsibilities It is true that the teaching of English law was introduced at Oxford as far back as 1754, when Sir William Blackstone delivered his famous lectures there, but the experiment attracted no professional students, and exerted no direct influence on legal education It was not until the movement inaugurated by the Incorporated Law Society and the Council of Legal Education of the Inns of Court had gained considerable momentum that the universities awoke from their lethargy and established what may be called schools of law These include, besides the venerable studies in the Roman law, upon which the chief emphasis is still placed, courses in general jurisprudence, English constitutional law and history, international law, and in the principal topics of English law. Apparently these attract but few candidates for the bar, and the legal profession, as of old, pursues its own course. The character of the instruction provided by the latter is largely determined by the time-honored division of the professional field between the two distinct orders of solicitors and barristers The honorable societies which constitute the four Inns

of Court are gilds of barristers, and the education provided by them is confined to candidates for the bar in the restricted English sense of that term. It was to meet the demand for more systematic training for the neglected solicitor's clerk that the Incorporated Law Society (now the Law Society of the United Kingdom) has instituted examinations to test the proficiency of students in the principles of law and procedure. Quite recently the society has also opened some courses of instruction. Meanwhile in the Inns of Court the potential barrister may, if he so desires, pursue courses of lectures in the whole field of English law as well as in Roman law, jurisprudence, and international law. But he is not required to do so, and it is reported that he seldom does. The new university foundations in London, and several of the provincial centers — Manchester, Liverpool, Leeds, and Sheffield — have also set themselves, somewhat feebly as yet, to the teaching of the law of the land.

The looseness and lack of consistency of the scheme of legal education in England renders it a difficult task to describe it as a whole, or to characterize it fairly. It seems as yet to be without form and void. The two older universities are still out of the current of professional influence. Their emphasis is still on the law of the dead past rather than of the living present, and they have not sought to establish any relation between the two. Then courses in English law are too general in character to be of much use to the professional student, and it is doubtful if he would avail himself of them if they were perfectly adapted to his purpose. The tradition of the bar still strongly favors a "practical" education, obtained principally in a law office, with enough reading of the standard textbooks to enable the student to pass the prescribed examinations. As it is of no particular advantage to him to attend law lectures, he is in general content to do without them. It is reported that the total number of law students registered in the universities and the Inns of Court does not exceed 2000, a much smaller number than the Inns alone harbored in the sixteenth century. The lectures in the Inns, like those in the universities, are for the most part of the didactic sort, often consisting of dictation. The "case method," which is revolutionizing the teaching of law in America, is spoken of with respect, but is nowhere employed. It may be added that there is no uniform standard of preliminary education for law students, that the courses of instruction are short, — not more than a year being devoted to the English law in most schools, — and that, excepting in the older universities, the instruction is for the most part given by members of the active bar. The only "system" that can be detected is the system of examinations. These are substantially the same in all the universities, in the Inns of

Court, and in the Law Society, and are said to be of a rigorous character.

It is apparent that much remains to be done to make the legal education of England the efficient instrument of legal progress that the times demand. But we are told that there is much ground for encouragement, that the bar is awakening to the need of reform, that the universities and Inns are feeling the influence of the American renaissance of the last two decades, and that a new Society of Public Teachers of Law in England and Wales has recently been formed to organize and push forward the work of legal education in the mother country of the common law. As Professor Hazeltine of Cambridge says, "These are happy auguries for the future."

**The Continent of Europe** — The American law school has for more than fifty years held the admiration of the profession in England, and has received unstinted praise from the leaders of that kindred bar — a fact which a comparison between the conditions of legal education in the two countries serves to explain. But no such acclaim comes from Continental jurists. For them the American system, even at its best, falls lamentably short of that ideal of sound scholarship which informs the legal education of the Continental countries of western Europe. As the inheritors of a tradition of world law, which was itself only the expression of natural law, a law written in the constitution of man, the jurists of Europe cannot regard the study of any isolated legal system, however developed and complete in itself, as in any proper sense a scientific performance. To the French or the German student, who regards his polity as only a fragment of a world order, the self-contained, self-satisfied attitude of the English and American lawyer seems narrow and provincial. It would be as reasonable, as scientific, to study the institution of the family without reference to the society of which it forms a part as to study the law of a given community without reference to the general law. Hence the Continental student refuses to be impressed with our claim that by making the study of the cases the basis of legal instruction we have made our teaching of the law scientific. He answers that a scientific method does not of itself make a science. He insists that the content of a subject of study is as important as the method of investigation employed upon it, and that until we have, through a new birth of scholarship, related our law to that of the rest of the civilized world, past and present, and to the ethical and social sciences, we shall never have a legal education worthy of the name.

This description of the conditions which have formed the ideal of legal scholarship on the Continent and determined the character of the legal education which there prevails points back of the universities to an order of ideas of which they are in part the fruit and

in part the preservers. As his law was the law of imperial Rome, the Continental lawyer, had there been no universities, could not have failed to conceive of the law that he was called upon to administer as only a part of the general European law. The law student acquired a knowledge of his own law through the study of the Roman law. But here the university was a necessary instrumentality. The law to be learned was not an indigenous common law, as in England, but a system handed down and "received," set forth in a language which only the learned know, and expounded in writings of great erudition which only the learned could interpret and expound. And thus, as the only depository of this learning and of the texts and other material on which it was based, the university became the seat of legal instruction. Its instruction was arid enough at first -- the scholastic interpretation of the inspired texts and of the scarcely less inspired gloss which encrusted it. But with the Renaissance a new spirit entered into the teaching of law, as into every other department of university education, and it was broadened and enriched by the study of philosophy and of general principles of jurisprudence. But it was not until the nineteenth century that the despised local law came to be accounted worthy of a place in the university curriculum, and not until the last quarter of the century that it was received as of equal worth and dignity with the Roman law. The new value which, under the reviving spirit of nationalism, has been put on the local common law in all continental countries and especially in Germany has contributed powerfully to this result.

*Germany* — But the European universities are not only the recognized seats of legal learning; they are also, through their relations to the government, the official gateways to the public service. Through them and in no other way is admittance gained to the bench, the bar, the high offices of state. This is pre-eminently true of the universities of Germany, which have long enjoyed the monopoly, and it is not too much to say that they have fairly earned it, through the combined practical and scientific character of the education afforded by them. The student matriculates at the university at the age of eighteen or nineteen on the completion of his course in the secondary school (*Gymnasium*). His studies, which cover the whole range of German as well as Roman law, include also international law, the philosophy of law, comparative jurisprudence, general and German legal history, and political science, and can usually be completed in three years. The instruction is mainly by lectures, with little or no discussion, though these are supplemented by seminars and *practica* for the more advanced and ambitious students. The lectures and other exercises are admittedly of a thoroughly scientific character, involving at every stage the consideration of principles

of a general and fundamental character. The student is encouraged to avail himself of the courses in philosophy (including ethics), logic, economics, and sociology given under the auspices of the faculty of philosophy, and it is said that few of them neglect to do so. On the completion of his course the student is subjected to a rigorous examination covering all the work done by him. If he is a candidate for the doctor's degree, he submits a dissertation on some topic in the law to which he has given special attention.

The course of "theoretical" instruction here outlined is the same for all law students, but there is a further course of "practical" instruction which varies more or less according to the career which the *referendar*, or graduate, intends to pursue. It will be borne in mind that in Germany the law is studied not only as a preparation for legal practice, but for the bench (there a separate profession) and for other branches of the public service. To confine our attention to the bench and bar, it may be said that the candidate for the latter is required to spend not less than four years, and the candidate for the former from eight to nine years, in the service of the state, as an *assessor* or assistant in the courts and in other legal positions, always under supervision and instruction, at the end of which time he again submits himself to an examination to test his fitness for the service for which he offers himself. Then and not until then is the systematic legal education complete.

*France* — The uniformity which, combined with a wide range of freedom in the election of courses and instructors, characterizes the system of university instruction in law in Germany, is lacking in the French universities. The system which there obtains is one of great flexibility, adapting itself to that one of the half dozen or more branches of the legal profession which the student proposes to enter. Nevertheless, as all but a comparatively small number pursue the complete course of study leading to the degree of licentiate in law (*licence en droit*), the more restricted courses which prepare for the lower grades of the profession, (*avoués*, notaries, and *huissiers*) may be neglected. The student who aspires to become an *avocat* or magistrate, or, indeed, to enter any of the higher grades of the public service, matriculates at the university, as in Germany, on the completion of his course in the *lycée* or secondary school. He is a year or two younger than the German student, but is more serious-minded and wastes little or no time in getting down to work. The character as well as the scope of the instruction imparted is well expressed in a paper on "The Teaching of the Law in France," read by Thomas Barclay of the French bar, before the American Bar Association in 1899. The teaching of the professors (of whom there are thirty eight in the law faculty of Paris), he tells us, "is distrib-

uted with a view to enable the student to take the degree of *licence en droit* at the termination of an ordinary three years' course of university study. There is an examination at the end of each year, and no student for the degree of *licence* can enter for either of the three examinations out of their prescribed order.

"The subjects of the first year's study are as follows. *Roman law*—the lectures on this subject embrace the whole of the legal institutions of Rome, with a view to initiating the student into the part which history plays in the development of law. *History of French civil and constitutional law*—here the idea is to awaken in the student that interest in tradition, and at the same time that critical understanding of laws by reference to their origin, which will bring him to respect their character without making him a slave to their form.

"In the same order of ideas there is a course of lectures for the first year's student in *Political Economy*, treated with regard to the current development of legislation, on the assumption that he will be enabled to understand a law better if he sees the reason for it. Lastly is included about one third of the contents of the *Civil Code* in which the lecturer endeavors again to explain why the law is as it is, and, as far as possible, to connect its provisions with the ethical basis upon which it rests.

"The second year's study includes another one third approximately of the matters treated in the *Civil Code*. The study of Roman law continues, but in this year it is treated with special reference to what contemporary French law has borrowed from it. In this year also the student must attend lectures on *criminal law*, *administrative law*, and *public international law*.

"In the third year he takes the remaining one third of the contents of the *civil code*, and *commercial law*, *private international law* and *civil procedure*."

Though this university training, culminating in the *licence en droit*, is a necessary stage in the evolution of the French lawyer, he is not entitled to call himself an *avocat* or to practice as such in the higher courts until he has also devoted three years to "assiduous attendance at the hearings in court" and has carried on practical work and discussions under the direction of the "Order of Advocates."

*Other Countries*—The legal instruction in other continental universities does not differ in important respects from that given in Germany and France. In some more attention is paid to the philosophy of law and to general and comparative jurisprudence than in others, and in the universities of Austria and Italy to economic history and theory, to social legislation or to ecclesiastical law, but the spirit which animates them is everywhere the same. Law is treated as a branch of social science, having its roots in ethics and in the history of civilization, and accordingly as a true university

discipline to be studied in the spirit of scholarship and science. The only conspicuous defect in the continental scheme of legal education is its complete neglect of that great system of the common law which divides the hegemony of the western world with the Roman law.

**LAW, WILLIAM** (1686–1781) — English divine and mystic, born near Stamford in Northamptonshire. He graduated at Cambridge in 1705, and was ordained in 1711. Owing to his Jacobite views, he was deprived of his degrees in 1713. As a non-juror he was excluded from preferments in the Church. Law was a prolific writer in the field of theology, and for one work, *Christian Perfection*, he received a gift of £1000, with which he founded a school for girls at King's Cliffe. In 1745, through the help of the widow of one of his admirers and a friend, he founded a school for boys and almshouses at King's Cliffe. Law and his two friends lived as nearly as possible according to the principles laid down in his most important work, *A Serious Call to a Devout and Holy Life* (1728). Here he devotes some chapters to education, and attacks the

## LAWN TENNIS

prevailing system as tending to pride, vanity, and ambition. The only basis of education is Christianity; hence humility and meekness are its ends. The method accordingly should be the study of the experiences of men who have led Christian lives. In the same way girls should not be trained up to value nothing but personal beauty, rather should they learn to live for their own sakes and the service of God. And it was along these lines that the *Rules to be observed by Girls* at the King's Cliffe School were drawn up. While Law's works have been neglected, his influence may be measured by the work of the Wesleys, Whitefield, and other evangelical leaders who frequently visited him.

**LAWN TENNIS** — This game is very modern in its present form, though it had its prototypes in comparatively distant ages. There are records showing that crude games of the lawn tennis type were played in Italy and in France several hundreds of years ago. One of these crude games, *la longue paume* of the French, was carried to England, and was probably the forerunner of modern lawn tennis. In 1874 Major Wingfield introduced a game under the name of *sphairistike*, which was gradually modified and the name changed to lawn tennis, and in 1877 definite rules were drawn up and the first championship contest held. Since 1877 lawn tennis has spread throughout England, the British colonies, America, France, — everywhere, in fact, where two or three Englishmen are gathered together.

The reasons for the great popularity of this game are many. It requires but a small piece of level ground, it is adapted to both sexes, all ages, and various degrees of strength; it is intensely interesting, it may be played by two, three, or four persons, and, like croquet and golf, it is a distinctly social game. One of the most difficult problems in physical education is to teach students in our schools and colleges forms of exercise which may be kept up after graduation. Lawn tennis fulfills this condition in a larger measure than any other game or sport. The popularity of lawn tennis is attested by the fact that it is the most widespread game in the colleges and secondary schools of the United States, 97.6 per cent of the colleges have from one to fifty-two tennis courts.

A tennis court may be laid out on a smooth lawn or a surface of clay and gravel. The dimensions for a single court (for two players) are 27 by 78 feet, a double court (for three or four players) is 36 by 78 feet. It is necessary to have at least 8 feet clear on each side and 20 feet at each end. The directions for laying out tennis courts, the rules of the game, and

## LEANDER CLARK COLLEGE

other kinds of information concerning the conduct of tournaments, etc., are described in detail in the *Lawn Tennis Guide*, published annually (Boston, Mass.).

**LAWRENCE COLLEGE, APPLETON, WIS.** — A coeducational institution founded in 1848 as an academy, with the title Lawrence Institute. In 1849 the title was changed to Lawrence University, and in 1908 to Lawrence College. Collegiate music, expression, and art departments are maintained. The entrance requirements are fifteen units. The college offers a four-year course leading to the degree of A. B. A pre-engineering course fitting students to continue a professional course at the University of Wisconsin is also offered. There is a faculty of forty-three members. The enrollment of students in 1911-1912 was 450 in the college.

**LAWS, SCHOOL** — See LEGISLATION, EDUCATIONAL, SCHOOL LAWS AND DECISIONS

**LEACH, DANIEL** (1806-1891) — School superintendent and textbook author, born at Bridgewater, Mass. He received his secondary school training at the Bridgewater Academy, and was graduated from Brown University in 1830. For several years he taught in the public schools. For ten years (1838-1848) he was principal of the Classical High School at Roxbury (Boston). From 1848 to 1855 he was one of the agents (supervisors) of the State Board of Education of Massachusetts, and from 1855 to 1884 he was city superintendent of the schools of Providence, R. I. He was active in the educational associations of New England, and was a frequent contributor to educational journals. He published three textbooks — an arithmetic, a spelling book, and a geography. W. S. M.

**LEANDER CLARK COLLEGE, TOLEDO, IA.** — A coeducational institution founded in 1856 under the auspices of the United Brethren Church at Shueyville and moved to its present location in 1881. It maintains an academy, college of liberal arts, teachers' course, music, business, elocution, and fine arts courses. The entrance requirements are about fourteen units. The college confers the A. B., A. M., and M. S., the two latter on completion of a year's residence and the presentation of a thesis. In 1910-1911 the enrollment was 262 students, of which 78 were in the college. The faculty consists of eighteen members.

**LEARNED SOCIETIES** — See ACADEMIES, INSTITUT DE FRANCE; SCIENTIFIC SOCIETIES, GERMANY, EDUCATION IN, and articles on other national systems

**LEARNING.** — The process whereby experiences are gained which function effectively in meeting new situations. This process may take many different forms, and what is popularly called learning is usually a complex process involving many of these forms. All learning presupposes on the part of the learner a stock of innate dispositions and instinctive tendencies which are the foundation for all acquired responses.

The simplest type of learning is the formation and development of perceptual processes. The stimulation of the sense organs is both logically and genetically the beginning of the learning process. Such stimulation leads to the organization of perceptual experiences. The importance of building upon such a concrete foundation has been frequently emphasized in educational theories, but there is always a tendency to fall back upon the symbolic and formal without a sufficient concrete perceptual basis. True perceptual development demands much more than mere presentation of the objects of the external world to the pupil. It cannot be taken for granted that children will recognize the true character of objects thus presented. Perceptual development demands the careful analysis of objects into their elements through observation and the fusion of these elements into new wholes.

The second type of learning is the acquisition of bodily habits, which frequently goes forward in connection with the progress of perceptual learning just mentioned. Habits may arise directly from instincts, in which case there is little, if any, of the learning processes involved. They may also arise by the method known as that of "trial and success." This method of learning is typical of both man and the lower animals. An unusual situation, or one for which no organized response is already present, calls forth diffuse movements, some of which are accidentally successful and tend, therefore, to be repeated, while the unsuccessful movements are gradually eliminated and an habitual mode of response established. The older education neglected this aspect of the learning process, which is emphasized in the modern subjects of manual training, drawing, etc.

The acquisition of language, written and spoken, is the most important of all human habits, because of its connection with the third type of learning, which belongs essentially to man, namely, the acquisition of power of response through the medium of ideas. Ideas are transmitted by means of language and retained by means of memory; hence, the popular use of the term "learning" as equivalent to memorizing.

In the work of the schoolroom most of these

forms of learning are combined. The process of learning to read, for example, involves the perceptual recognition of words and sentences, the motor responses of eye and voice, and, if the reading is not merely mechanical, the acquisition of ideas. E. H. C.

**LEAVES OF ABSENCE** — By this is meant leaves of absence for a term, or year, granted to teachers, for good reasons and frequently on partial pay, their positions being held for them until their return. Such leaves of absence are common in the larger universities, where the sabbatical leave is a well-established institution. In such institutions the teacher is allowed to spend each seventh year in absence on one half, two thirds, three fourths, and sometimes on full pay. In a few of our larger institutions the half-sabbatical is also allowed, a half-year on partial pay being allowed after each three years of service. In the smaller colleges and in the state normal schools such leaves on pay are seldom granted, and, when granted, are more frequently granted for long and meritorious service than as a regular privilege for all. As the salary of the instructors in such institutions is usually so small that they cannot afford to take vacations at their own expense, such leaves of absence for study are seldom taken except by young instructors who are trying to complete their studies for a university degree. The result is that these institutions suffer because their instructors lack contact with men in their own lines in other and in larger institutions. The summer session of the larger universities, however, is doing much to remedy this defect.

In the public schools such leaves of absence for study and travel are confined entirely to a few large cities. Many cities are so far neglectful of their own interests that they refuse to grant leaves of absence to their own teachers, even when they are willing to travel and study at their own expense. In a few cities, such as Boston and Rochester, the plan of granting to teachers a year off from time to time for purposes of travel and study has been adopted, but the number of such cities is as yet very small. Both Boston and Rochester provide for vacations for purposes of travel and study after seven years of service, on half pay, and Boston has provided further for years of rest on full pay for long and meritorious service. A few other cities, as for example Omaha, have adopted the plan of granting leaves of absence for study to those teachers who are willing to take them at their own expense, and, in lieu of

## LEAVING CERTIFICATE

any pay while absent, granting salary increases on the basis of such study on the return of the teachers to the school system. Probably few things would be of greater value to teachers in the elementary schools of our cities than an occasional year off on partial pay for purposes of travel or study, and the extension of the plan of sabbatical leaves is one of much importance. Certainly leaves of absence without pay for any worthy educational purpose ought to be granted cheerfully by Boards of Education.

E. P. C.

**LEAVING CERTIFICATE** — A form of certificate granted to pupils in elementary or secondary schools, carrying with it certain privileges. In elementary schools such certificates indicate that the pupils have completed certain required work, years, or courses, or have been in regular attendance for a certain time, and are usually used as permits to go out to work. Such a certificate has been in existence in France for thirty years, where it is given, on the basis of a public examination, to those pupils who have completed the primary school course and have reached the minimum age of eleven years. The examination covers only the subjects studied in the elementary schools up to the completion of the *cours moyen*, and the certificates awarded (*certificat d'études élémentaire*) are much esteemed by French children and parents, and are almost a prerequisite for employment of any kind. Another certificate marking the attainment of a somewhat higher stage is the *certificat d'étude primaire supérieure*. (See FRANCE, EDUCATION IN.)

In England local authorities may frame by-laws regulating the total or partial exemption of pupils from school attendance, and in addition may insist that such pupils obtain from an Inspector of the Board of Education a certificate of proficiency to the effect that a candidate has attained the standard of the grade which he should have reached by age. No certificate is granted below the fourth standard or grade. The whole matter is now under consideration of the authorities.

In the United States there is no certificate as such, though the elementary school, or grammar school diploma, granted almost everywhere, is in effect a somewhat similar certificate, but much less highly esteemed by both pupils and employers than is the case in France. Diplomas of graduation are commonly granted to those who complete the eighth grade (in some cases still the ninth) of city schools, and generally the ninth grade (though frequently the eighth, and, in some parts of the South, the sixth) in rural schools. In most cases diplomas signed by the city or county superintendent of schools, or the county board of education, are issued to the graduates, and graduating exercises of a somewhat formal character are very frequently held. To many this marks

## LEAVING CERTIFICATE

the completion of their school course, and the diploma thus becomes for them a leaving certificate. The diploma has an academic value almost entirely, and is of use to the pupil only in case he or she desires to enter a high school. In itself it is seldom required or asked for as a prerequisite to employment, and no such importance is as yet placed on its possession as is the case in France.

So far as leaving certificates are granted, they partake of the nature of work certificates, or age and schooling certificates. These are granted in almost all states where a child-labor law is strictly enforced, and they thus become a prerequisite for employment in the case of young persons. A common form is a certificate from the school authorities, stating the pupil's age, and certifying that he is entitled to employment at certain kinds of labor and for certain hours. Pupils from fourteen to sixteen are commonly required to hold such permits, and all illiterate minors, over sixteen, in some states must present evidence of attendance at evening schools to be entitled to employment in the day time. These certificates must be kept on file by the employer, and exhibited, on request, to attendance officers and labor inspectors. Massachusetts presents an excellent example of the employment of this kind of a leaving certificate. Two other forms of such permits, or certificates, are commonly granted. One is a permit to school children, usually between the ages of twelve and fourteen only, granted by the school authorities or the juvenile court judge, on evidence of parental need for the labor of the children, permitting them to engage in certain forms of light labor during certain specified hours. Badges are sometimes used, as in the case of the New York City newsboys. The other form of labor permit or certificate is that permitting children who have been in regular attendance at school during the preceding year to engage in certain forms of labor during the summer or other vacation. Such permits state the age, define the time limits of the vacation, and specify the kind of labor permitted. (See CHILD LABOR, ENGLAND, EDUCATION IN, FRANCE, EDUCATION IN, PART TIME SCHOOL ATTENDANCE.)

Leaving certificates from secondary schools are usually granted to candidates who have reached at least the age of sixteen and have attained a certain standard in secondary school subjects. Most frequently such certificates serve to exempt their holders from other examinations required for entrance into the universities, or certain professions, *e.g.* in England, accounting, medicine, architecture, etc. School leaving certificates may be granted by the State, as in Germany and France, or by universities, as in England and America. In Germany there are two types of leaving certificates, the *Einjährigenschein*, or certificate for admission to one year of military service,

## LEAVING SCHOOL

granted at the end of a six-year course in a secondary school, and the *Abiturenprüfung* (*q.v.*), granted at the end of a full nine-year course. In France the leaving certificate is the *Baccalauréat* (*q.v.*) In England there are numerous examining bodies which grant such certificates; the most prominent are the Oxford and Cambridge Joint Board, the Joint Matriculation Board of the Northern Universities, the University of London, and the College of Preceptors. Each university also conducts its own matriculation examinations and system of school inspection, and in many cases the certificates granted are equivalent to leaving certificates. The tendency to establish some system of interrecognition of certificates is at present being considered under the Board of Education, but there is not much likelihood that any general, state-wide certificate, conducted by the central board, will be introduced (See England, Board of Education, Consultative Committee, *Proposals for a System of School Certificates*, London, 1904, and *Report on Examinations in Secondary Schools*, 1911.) In America school leaving certificates are found commonly in the Middle West and the West, along with the general system of accrediting schools.

See ACCREDITED SCHOOLS, ENGLAND, EDUCATION IN, EXAMINATIONS, FRANCE, EDUCATION IN, GERMANY, EDUCATION IN; and other national systems

**LEAVING SCHOOL** — See COMPULSORY ATTENDANCE; RETARDATION AND ELIMINATION OF PUPILS; LEAVING CERTIFICATES

**LEBANON UNIVERSITY, LEBANON, OHIO** — A coeducational institution organized in 1855 as the Southwestern Normal School. The present title was adopted in 1907, and in 1908 by an act of the Ohio legislature the university became a part of the city school system, supported by city tax. Colleges of liberal arts, of business methods, fine arts, a college for teachers, a school for agriculture, summer school, preparatory school, and a university extension department are maintained. More than 4000 students have received a part of their education in this institution.

**LEBANON VALLEY COLLEGE, ANN-VILLE, PA** — A coeducational institution established in 1866 under the auspices of the United Brethren Church. Academic, college, music, and art departments are maintained. The entrance requirements are fifteen units. Classical, chemical-biological, mathematical-physical, historical-political, and modern language courses are offered, leading to the degree A.B. Of 232 students enrolled in 1910-1911, 119 were in the college department. The faculty numbers twenty-one members.

## LECTURE SYSTEMS

**LECONTE, JOSEPH** (1832-1901) — Scientist, university professor, and textbook author, educated at the University of Georgia, the New York Medical College, and the Lawrence Scientific School of Harvard. He was professor in the University of South Carolina (1856-1869) and the University of California (1869-1901). He assisted Professor Louis Agassiz (*q.v.*) on his scientific expedition to the coast of Florida. He was the author of *Elements of Geology* (1878), *Compend of Geology* (1884), *Comparative Physiology* (1900), and of one hundred and fifty scientific and philosophical papers. W. S. M.

**LECTURE METHOD** — Any use of extended, formal discourse for the presentation of knowledge to students may be included under the lecture method. It has its largest value and its widest use among mature students and in those subjects where an objective method cannot be readily utilized. Hence its wide use in colleges and universities, where almost all fields, save those of linguistics and the natural and applied sciences, employ it as the dominant method of instruction. The lecture method is only slightly used in the high school, and not at all in the elementary school, save in the highly amended form of short and intermittent talks. Its restricted use in the lower schools is due to the obvious limitations of the method. The instructor has no way of knowing as he proceeds that each point and its relation is mastered, and the student himself is not given the opportunity for interruption in case of failure or doubt in grasping the argument, which would be the case where the method of discussion is utilized. The response of students in the lecture room is receptive rather than active, and the impressions, being given by verbal means with little or no chance for objective or other visual demonstration, are likely to be abstract and verbal, if not actually hazy. H. S.

See INFORMATION TALKS, also the section on method in the articles on the various academic subjects

**LECTURE SYSTEMS** — The provision of lectures for the public has become widely ramified and has assumed many forms. The system of free public lectures maintained by school authorities, now one of the most widespread, at any rate in the United States, is of recent origin, and was inaugurated in New York in 1889. Free lectures had been provided by the American Museum of Natural History in 1884, but only for teachers. The total number of lectures given in 1909-1910 was 1654 (literature, history, sociology, art, 854, general and applied science, 318, descriptive geography, 391, Italian, Yiddish, and German, 91). These were attended by 959,982 persons, while 134 local superintendents and 56 stereopticon operators were employed. The

system was adopted by many large cities, *e.g.* Boston (1896), Philadelphia (1898), Chicago (1897), Newark, Cincinnati, Rochester, and many others. Generally the lectures originated from the activity of clubs or associations, *e.g.* at Boston through the Twentieth Century Club and the Home and School Association, and at Philadelphia through the Home and School League, which worked in connection with school authorities, providing lectures and receiving the use of school buildings. This phase of the subject will be treated under the **SCHOOL AS A SOCIAL CENTER**. It is also in connection with the school that some city systems and private schools have instituted special lecture courses to which the parents of scholars are invited, and which are afterwards discussed by parents and teachers (See **PARENTS AND SCHOOLS**). Another form of this activity is found in connection with museums in which popular scientific lectures are given in connection with the exhibits (See **BOTANY; LIBRARIES, MUSEUMS**). In addition to these systems of free public lectures, numerous clubs and associations have provided and continue to provide semi-public lectures and courses. Of these the chief may be mentioned, and will be found treated under separate heads **CHAUTAUQUA, CONCORD SCHOOL OF PHILOSOPHY AND LITERATURE, COOPERATIVE HOLIDAYS ASSOCIATION, LYCEUM, MECHANICS INSTITUTES, Y M C A**. Of a more formal character, and differing from public lecture systems in being specialized and technical, and in most cases consisting of courses of lectures, are those conducted for the training of teachers in service (see **INSTITUTES, TEACHERS, TRAINING OF**), for the improvement of agriculture, conducted by agricultural boards and university departments of agriculture (see **AGRICULTURAL EDUCATION**), for further education of adults conducted by private organizations, public school authorities, and universities, see **ADULT EDUCATION, UNIVERSITY EXTENSION, WORKING MEN'S COLLEGES; WORKERS' EDUCATIONAL ASSOCIATION**.

**LEE, ROBERT EDWARD.** — General Lee's work as an educator only is here considered. Born in Westmoreland County, Virginia, 1807, Lee graduated from the U. S. Military Academy in 1829, with the very unusual honor of a perfect record. Subsequently (1852-1855) he served most ably as superintendent there, gaining an experience useful in his later educational work. At the close of the Civil War, Lee was the idol of the South, and the most respected in the North of all who had been connected with the Confederacy. Bereft of his profession, broken in fortune, he nevertheless declined the offer of an independent estate in England, and refused likewise to lend his name to remunerative financial enterprises. The very esteem in which he was held fixed in him the determination to contribute personally to

the rehabilitation of the South. With neither inclination nor aptitude for statesmanship, he selected the field of education as the one in which he could render his best service. Feeling that he belonged to the whole South, he refused the headship of a denominational college. Fearing political entanglements, he declined overtures from the state university of Virginia. Instead he accepted (September, 1865) the presidency of Washington College (now Washington and Lee University, *q.v.*). This institution had been endowed by Washington, but the disasters of the late war had scattered its funds, while a hostile army had destroyed its equipment and all but wrecked its buildings. To the upbuilding of this college as a social agency Lee gave the remainder of his life. His general policy was to make the college course "practical" in order to meet the pressing needs of the devastated section. Departments of engineering and "applied chemistry" were introduced, and a school of commerce planned. To render these newer courses more accessible, the uniform curriculum gave way to the elective system. The success of the new president was in all respects preeminent. In the words of one of his colleagues, "he found the college practically bankrupt, disorganized, deserted, he left it rich, strong, and crowded with students. . . he gave it organization, unity, energy, and practical success." The influence of his personality on the student body was not the least of his successes.

Upon Lee's death (Oct. 12, 1870) the college, feeling itself justly entitled to the honor, had its name changed to Washington and Lee University (*q.r.*) W. H. K.

#### LEEDS, UNIVERSITY OF, LEEDS, ENG.

— One of the recently founded English universities. The university had its origin in the Yorkshire College, which was formed in 1884 by the amalgamation of the Leeds School of Medicine (1831) and a college of science (1874). From 1887 to 1903 the college was a constituent part of the Victoria University, together with Owens College, Manchester, and University College, Liverpool, and remained such after the last body obtained a university charter. In 1904 Yorkshire College obtained a charter and became by act of Parliament the University of Leeds, with all the usual power appertaining to such a body, "to do all such things as may be requisite, . . . to cultivate and promote arts, science, and learning." The governing body consists of the Court, which is formed by the Chancellor, Pro-Chancellor, Vice-Chancellor, and Pro-Vice-Chancellor, and representatives of the universities and schools, of local councils, of benefactors, of the Crown,

and others. The Council is the executive body, and the Senate has the general regulation of academic work. The university is maintained by endowments, donations from different sources, government grants, grants from city and county councils in the Ridings of Yorkshire, and student fees. The Clothworkers' Company of London gives an annual subsidy of £4000, and has provided buildings for instruction in dyeing, textiles, and tinctorial chemistry, while the Skinners' Company supports a department for instruction in subjects appertaining to the leather industries. Work is offered in departments of arts, commerce, law, science and technology, medicine, and dental surgery. With the university are affiliated the Huddersfield Technical College, and the College of the Resurrection, Mirfield. Evening classes and extension courses are given. With the aid of the county council of the North, East, and West Ridings the university conducts agricultural courses and experiments, and sends lecturers and dairying instructors to various local centers. While the general cultural work is strong, the applied sciences receive especial attention. Classes and laboratories are open to men and women on the same terms. The university is not residential, but facilities are afforded for the accommodation of students, who, however, are drawn in the majority from a radius of thirty miles of the city. As in the case of the other universities recently established, considerable progress has been made especially in adaptation to local needs and interests. Professor Michael E. Sadler was appointed Vice-Chancellor of the university in October, 1911. The enrollment in 1911-1912 was 901, with a teaching staff of 152.

**LEHIGH UNIVERSITY, SOUTH BETHLEHEM, PA** — Founded in 1865 as a result of the gifts and bequest of Judge Packer, amounting to \$2,000,000. The aim of the university is to provide technical, literary, and scientific preparation for the type of work demanded by the resources of the region. The institution is well equipped with large laboratories to give

instruction in civil, mechanical, metallurgical, mining, electrical, and chemical engineering, and in electro-metallurgy, chemistry, and collateral studies. The entrance requirements are fourteen units. The university confers the degrees of A.B. and B.S. and the various degrees in engineering. A special course is also provided for teachers, a psychological laboratory and a practice school being maintained. In 1910-1911 the number of students enrolled was 655. The faculty consists of seventy-three members.

**LEHR- UND LERNFREIHEIT.** — See FREEDOM, ACADEMIC

**LEIBNITZ, GOTTFRIED WILHELM, FREIHERR VON** (1646-1716) — One of the two or three most universal minds in modern history, contributed new ideas and projects of fundamental reform to nearly all the larger provinces of inquiry and practice, education among them. His place in educational history is scarcely comparable to that which he holds in mathematics (as the inventor, simultaneously with Newton, of the calculus), in logic, in metaphysics (theory of monads), and in rational theology (as the chief representative of the eighteenth-century type of optimism). His father, professor of ethics and law at Leipzig, dying early, the boy was largely self-taught, by omnivorous reading in his father's library, he declares that he learned far more than at school. His studies met the opposition of his schoolmaster, who, finding him reading Latin for pleasure, endeavored to arrest this "premature" erudition, and to restrict his pupil to the catechism and the *Vestibulum* of Comenius. This experience left its impress upon Leibnitz's educational theory, he was always strongly convinced of the folly of treating all children by the same rules and of the danger of quenching the child's natural intellectual curiosity by task-work. Leibnitz received his baccalaureate at the University of Leipzig at seventeen, next studied mathematics at Jena, and took his doctorate in law at Altdorf in 1666. A decisive epoch in his intellectual development was a residence in Paris, 1672-1676, interrupted by travel in England, at this time he came into contact with the full stream of new ideas in philosophy, mathematics, and the natural sciences. During part of the same period, he had his one experience in practical pedagogy, acting as tutor to the sixteen-year-old son of his former patron, the Baron von Boyneburg, the subsequent career of the pupil was not discreditable to the teacher. In 1676 Leibnitz took the post of councillor and librarian to the Duke of Hannover (Brunswick-Lüneburg), in this service, save for several extensive journeys, he continued till his death, forty years later. His manifold scientific interests and his endless ingenious plans for the advance-

ment of civilization — which ranged from a scheme of compromise by which he hoped to reunite Protestants and Catholics, to the invention of a calculating machine — involved him in a voluminous correspondence with over a thousand persons, including most of the important scholars, philosophers, statesmen, and sovereigns of Europe. This prodigious epistolary activity prevented him from giving any adequate connected presentation of his philosophy. Convinced of the dependence of public welfare upon the progress of science, and of the dependence of the progress of science upon cooperation and organization, he brought about under royal patronage the creation of the Society (afterwards Academy) of Sciences of Berlin, and sought to persuade Peter the Great and other monarchs to establish comprehensive institutions for research and the diffusion of knowledge.

The general philosophy of Leibnitz, one of the most involved, technical and, at first acquaintance, paradoxical in modern thought, cannot otherwise than misleadingly be set forth in brief space. The part of it most nearly pertinent to educational theory is the epistemological doctrine of the posthumous *New Essays concerning Human Understanding*, 1765 (English tr., Langley, 1896), a polemic against Locke's sensationalistic account of the origin of ideas. Other of the important philosophical writings of Leibnitz may be had in English translations by Duncan, 1890, Latta, 1898, and Montgomery, 1902.

The direct contribution of Leibnitz to educational theory is to be found chiefly in a brief work written in his twenty-first year *Methodus nova discenda docendaeque jurisprudentiae* (pub. 1667). The book is chiefly a treatise on the study of jurisprudence, but the first part of it deals with intellectual education in general. It is characteristic of Leibnitz that he defines both the process and the end of education in terms of activity, its aim is "the acquisition of a permanent readiness for action" of any desired sort (*agendi promptitudinem acquisitam permanentem*). Such acquired power of action, or *habitus*, may characterize anything capable of action, even inanimate things. The process by which it is acquired is "habituation" (*assuefactio*), or a "making accustomed" to the desired activity itself. Education is thus for Leibnitz merely the highest form of a process which is exemplified even in the inorganic, — as when by bending metal rods we accustom them to recoil in a certain way. With animal training, in particular, the training of children is closely related. "Since infants in their early years do not greatly differ from the brutes, their instructors might not unprofitably borrow something from the methods of the teachers of animals." The term *doctrina* covers the process of "habituation" in all sentient beings, animal or human, *institutio* is the special form

of it adapted to the training of the rational animal. At all its levels "habituation" depends chiefly upon two factors: the frequency (*multitudo*) of the impressions made by the practice acts, and their intensity (*magnitudo*). In teaching, the former requires very frequent reviews — not merely "annual reviews, as in the ordinary schools, but daily, weekly and monthly" as well. The latter demands that each repetition have *quamdam vim imprimendi*, i.e. a power of actually making an impression on the child. This may be gained partly by associating the matter taught with vivid sense impressions, preferably of more than one sense. Both can best be realized by a carefully graduated increase in the attainments demanded. Throughout, it is important that the acquisition of the *habitus* be made agreeable (*jucundum*), either by showing its connection with attractive ends, or "by the use of means that are themselves agreeable." That children ought so far as possible *discere ludendo*, "to learn by playing," is one of Leibnitz's most constant and characteristic contentions. Teachers must so act that the pupils "may of their own accord (*sponte*) make themselves more capable of learning." Leibnitz, therefore, recommends the use of alphabetical blocks, pictures, instructive games, and of the *Orbis pictus* of Comenius (*qv*), which pupils should be set to paint in appropriate colors. In order that the maximum instruction may be accomplished with the least possible fatigue of the pupils, only part of the day's lesson should be studied by any one child, then, "while he recites the others will, by listening, learn his portion as if at play."

The course of instruction should be divided into four periods. During the first, that of infancy, the child should learn at home the vernacular, Latin, and some history. If he talk Latin in the morning with his master and fellow pupils, "and the vernacular the rest of the day with the women and servants," it is quite possible for a knowledge of two languages to be acquired simultaneously at an early age. From his sixth to twelfth year the child should attend the public school; "let him not live too much at home, in order that he may learn to care for himself." The studies of this period include a "more special knowledge of history," mathematics, *elegantiae verborum*, and several natural sciences, together with music and various physical exercises. From twelve to eighteen the youth should have more freedom, studying, "not under preceptors, but friends," in the university. Besides learning a number of sciences, French and Italian, and enough Greek and Hebrew to enable him to read the Bible in the original, he should "declaim publicly and act in stage-plays." The fourth period, beginning at eighteen (or twenty, in the case of those who mature slowly), should be devoted to travel and the study of the life, laws, and institutions, and the indus-

trial, commercial, and agricultural methods of foreign countries. To such studious *peregrinato* Leibnitz at this time attached great importance, not only for its benefits to the individual, but also as a means of promoting international good will, and of making the special attainments of each people eventually the possession of all. Later (1696), in his *Projet de l'éducation d'un prince*, he discountsenances early foreign travel for curiously chauvinistic reasons. But the principle *discere ludendo* is still reiterated.

The educational doctrine of the *Methodus Nova* is an extraordinary production for the seventeenth century. It is remarkable not only for what it contains, but also for what it is free from. There is in it none of that use of vague analogies from the "method of Nature" characteristic of Ratke and Comenius (*qq v*). So far as it goes, the method of Leibnitz is purely psychological.

In 1711 Leibnitz wrote to a friend that he had often contemplated a new edition of the *Methodus Nova* and an amplification of the part dealing with education in general. "There are, decidedly, some thoughts in this little book which even now I do not think ill of." This project of revision was never executed. But the book was reprinted in 1748, with a preface by Chr Wolff.

**LEIGH, EDWARD** (1642-1671) — Writer on the history of religion and learning, born at Shawell in Leicestershire. He graduated B.A. from Magdalen College, Oxford, in 1620, and M.A. in 1623. He entered the Middle Temple, and in 1625 spent six months in France. In 1640 he was elected M.P. for Stafford. He was a member of the Assembly of Divines, and colonel in the Parliamentary army. In 1656 he published a *Treatise of Religion and Learning and of Religious and Learned Men*, in which he advocates the "Syncretism of Religion or of a friendly reconciliation of the different parties amongst themselves." Of learning he distinguishes three types: (1) that which draws us to itself by its own force, *e.g.* virtue, knowledge, and truth; (2) that which is desired for fruit and profit, as money; (3) that which draws us both by its force and dignity and by profit. He then proceeds to show how learning has always

been appreciated, and points out the value of learning in different professions, especially the clerical. But human knowledge is valuable for practice, not for ornament or pride. In the Scriptures are "all the treasures of natural and moral philosophy, of politics, of poetry, of history, of mathematics, of metaphysics." Leigh still favors the seven liberal arts, and also recommends the study of mathematics, the civil and canon law, and oriental languages. He gives an account of universities at home and abroad, and in the latter part of the work adds a Biographical Dictionary of famous men in religion and learning. Another work by Leigh is *Three Diatribes or Discourses, First of Travel or a Guide for Travellers into Foreign Parts, Secondly of Money and Coins, Thirdly of Measuring the Distance between Place and Place* (1671). He points out the usefulness to society at large from the journeys of travelers, and gives examples of travel for study, and its value for the advance of the knowledge of foreign languages, although he regards the "Latin tongue" as still necessary for the traveler. For Leigh's references to books on travel, see TRAVEL, EDUCATIONAL VALUE OF.

Leigh was also well known for his *System or Body of Divinity wherein the fundamentals of Religion are opened, the contrary errors refuted*, 1654. In connection with scholarship, his most important production was *Critica Sacra or Philologicall and Theologicall Observations on all the Radices or Primitive Hebrew Words of the Old Testament in Order Alphabetically* (final form published 1662). This was "the best Hebrew-English lexicon of the age" (D M Welton, *John Lightfoot, the English Hebraist*, Leipzig, 1878). F. W.

**LEIGH, EDWARD** (1816-1889) — Educational writer and textbook author, graduated from Brown University in 1835, and three years later from the Andover Theological Seminary. For many years he was engaged in educational work in St. Louis. Author of *Illiteracy in the United States*, and readers, spellers, and other school books. W S M.

**LEIPZIG.** — See GERMANY, EDUCATION IN.

**LEIPZIG, THE ROYAL SAXON UNIVERSITY OF.** — The second oldest university in the present territory of the German Empire, having been established in 1409 by Papal Bull of Alexander V under Frederick the Quarrelsome, Landgrave of Thuringia and Margrave of Meissen, and his brother William, who welcomed the German students on their leaving the University of Prague under their professors Otto von Munsterberg and Johann Hoffmann as a result of university legislation in favor of the Bohemians. The University of Prague served in most particulars as a model. The first year

369 students were enrolled. The details of the early history of the institution are somewhat veiled in mystery, no definite information is available, for example, as to whether the university was composed from the very beginning of the four traditional faculties. Originally there were two "colleges," which served as homes of students and professors, but the student body rapidly outgrew these accommodations. By the close of the fifteenth century, Leipzig could boast of a larger attendance than any other North German university, and soon became for a time the most renowned institution of higher learning in Germany, as it is unquestionably one of the foremost universities of the world to-day. The establishment of a university in the neighboring town of Wittenberg in 1502 made serious inroads on the attendance at Leipzig, but from the close of the sixteenth century on, through the seventeenth century, the institution had a larger enrollment than any other German university. By the beginning of the sixteenth century Leipzig had become thoroughly saturated with the humanistic spirit. It was not until 1539, under the influence of Melancthon, that the principles of the Reformation carried the day, a complete reorganization being completed in the year 1559. At this time Leipzig was the wealthiest university in the land, but shortly afterwards a period of deterioration set in, which lasted for over a century, the institution being characterized by an ultraconservative spirit that looked askance at improvements and innovations. It was as a result of this spirit that Thomasius (*qv*) after his dismissal turned to Halle, and began his lectures in that city in 1690. (See HALLE, UNIVERSITY OF)

It was not until after the Napoleonic disturbances were over that significant internal reforms began to be instituted, in 1830 a complete reorganization was effected, and in the following year the erection of a new university hall furnished an important addition to the material equipment of the institution. Thirteen years later a dormitory and a lecture building were added, and soon after a period of building activity was begun which resulted in the erection of a whole series of institutes and clinics of one kind or another (for illustrated description see the *Festschrift* cited under References), of a splendid library, and of a new main building (completed in 1897), Leipzig in this respect being better equipped than most other German universities. The new *Aula* contains a colossal painting by Max Klinger, representing the development of Greek culture. For several decades large contributions have been made by the state, about three million dollars having been supplied for building purposes between 1878 and 1902. Inasmuch as the kingdom of Saxony has only one university to support, as against ten in Prussia, usually large funds are available for maintenance, the annual budget amounting to nearly one million dollars, a sum exceeded

in Germany only by the appropriations made for the University of Berlin. The library was founded in 1544 by Kaspar Borner, during whose administration as rector of the university (1539-1543) marked advances were made. The new building, which was completed at a cost of over one million dollars in 1891, contains 550,000 volumes and about 6000 Mss. The University of Leipzig is especially well supplied with institutes and departmental libraries, among which may be mentioned the Germanistic institute (11,000 volumes, Sievers), the institute for experimental psychology (Wundt), the pedagogical seminar, the physical-chemistry laboratory, and the *Institut für Kultur- und Universalgeschichte* (22,000 volumes, Lamprecht), of which the last, located in the *Haus zum goldenen Bären* (erected in 1736, and occupied by Gottsched up to the time of his death in 1767), deserves particular mention. The faculty of philosophy includes a department of agriculture with an agricultural institute, and a department of veterinary medicine with a veterinary clinic and a polyclinic.

Among prominent teachers associated with this institution mention may be made of Johann Christoph Gottsched and Christian Furchtegott Gellert in literature, Stobbe and Windscheid in jurisprudence, Cohnheim in pathology, Thiersch in surgery, Weber in anatomy, Curtius in classical, Wulker in English, and Hildebrand, Haupt, and Zarneke in Germanic philology, Wachsmuth in history, Roscher in economics, Overbeck in archaeology, Christian Hermann Weisse and Fechner in philosophy, Johannes Olarius and Julius Franz Dehtzsch in theology, Mobius in astronomy; Leuckart in zoology, and Wislicenus in chemistry. Goethe was a student at Leipzig from 1765 to 1768.

In the winter semester of 1911-12 there were 4900 matriculated students in attendance, Leipzig being the third largest university in Germany, and exceeded only by Berlin and Munich. Of these students 391 were enrolled in the faculty of theology (Protestant), 872 in law, 841 in medicine, 108 in dentistry, and 2816 in philosophy; in addition there were 925 auditors. The teaching staff consisted of 242 instructors, of whom 76 were docents. The King of Saxony is rector magnificientissimus, a rector magnificus being elected annually by the faculty.

The city of Leipzig also contains a commercial college founded in 1898 (about 500 students), a Royal Conservatory of Music, an institute for experimental pedagogy and psychology, established by the Teachers' Association of Leipzig in 1906, the library of the imperial court (159,000 volumes), a city library founded in 1677 (126,000 volumes), and a pedagogical central library founded in 1872 (over 150,000 volumes).

## LEISURE — See PLAY

**LELAND, CHARLES GODFREY** (1824-1903) — The American poet and author, exercised a profound influence in the movement for the introduction of the industrial arts in schools. In 1881 there was established under his direction the Public Industrial Art School of the city of Philadelphia, maintained from funds appropriated by the school board. Leland himself had charge of design, while all the other arts, modeling, painting, mosaic, pottery, carpentry, woodcarving, cabinet-making, metal work, embroidery, etc., were under the charge of, though not taught by, J. Liberty Tadd. The principle on which Leland based his experiment was that the race has developed the ornamental before the useful. Such work results in mental and moral improvement, forms the foundation for trade preparation, and, if generally introduced in all schools, public and private, would break down false notions about labor. Leland's work attracted considerable attention in America and Europe. The British Home Arts and Industries Association, of which Walter Besant (*qv*) was treasurer, was inspired by Leland's work (*Minor Arts*) and his school. Leland wrote many practical guides and manuals in various fields of industrial arts, his chief work on the general subject is his pamphlet on *Industrial Art in Schools*, contained in the *Circulars of Information* issued by the United States Bureau of Education (No 4, 1882).

**LELAND STANFORD JUNIOR UNIVERSITY, STANFORD UNIVERSITY, CAL** — A coeducational institution founded in 1885 through the gift of Mr and Mrs Leland Stanford in memory of their son. "Its object is to qualify students for personal success and direct usefulness in life." The university is located on the Palo Alto Farm in the Santa Clara Valley, thirty miles southeast of San Francisco. The grounds consist of over nine thousand acres, partly level and partly rising into the foothills of the Santa Cruz Range and overlooking the Bay of San Francisco. The central group of buildings is ranged round

two quadrangles, the one consisting of twelve, the other of fourteen buildings. The buildings of the medical department, which was established in 1908, are located in San Francisco, and are four in number, including the Lane Hospital. Fifteen units are required for entrance. A four-year course leading to the degree of Bachelor of Arts is offered. Tuition is free except in the professional courses of law and medicine. With the exception that English composition is a prescribed study in the first year for those who do not satisfy the matriculation test, the undergraduate work in all departments is elective. Students must select as their major subjects the work of some one department, and as minors some collateral work. Advanced courses are offered leading to the degree of Master of Arts, the professional degree of Engineer, Juris Doctor, Doctor of Medicine, and Doctor of Philosophy. The high school teachers' certificate is granted by state, city, and county boards of education, on the recommendation by the university, to candidates who have fulfilled the requirements of the State Board of Education. The grammar school teachers' certificate is also granted to graduates of the University on fulfilling the requirements. The University library contains 197,000 volumes, including the Hopkins Railway Library, the Thomas Welton Stanford Australasian Library, the Hildebrand Library, mainly of works as Germanic philology and literature, and the Jordan Library of Zoology, consisting of several thousand volumes and pamphlets on fishes. The Leland Stanford Junior Museum contains valuable collections of pictures, antiquities, pottery, laces, and curios. An active fraternity life has been developed among the students, many of whom live in the fraternity houses. The students enrolled in 1911-1912 numbered 1762, distributed as follows: graduates, 208, undergraduates, 1450; specials, 104, summer session, 59. Leland Stanford Junior University is one of the institutions on the accepted list of the Carnegie Foundation for the Advancement of Teaching. It has a productive fund amounting to \$21,000,000, and the income for 1910-1911 was \$886,550. The faculty consists of sixty-one professors, twenty-eight associate professors, thirty-seven assistant professors, and forty-six instructors, and one hundred and forty-seven lecturers and assistants. David Starr Jordan, Ph D, L L D, is the president.

**LELAND UNIVERSITY, NEW ORLEANS, LA** — A coeducational institution for colored students, incorporated in 1870, and owing its existence to the gifts of Mr Holbrook Chamberlain of Brooklyn College and normal departments, each with preparatory departments, music, manual training, and theological departments are maintained. A number of auxiliary schools are under the charge of the university. The entrance requirements are

## LEMBERG

equivalent to a four-year high school course. The college course leads to the degree of A B. The faculty consists of sixty-eight members. The enrollment in 1911-1912 in all departments was 1715.

**LEMBERG, THE IMPERIAL ROYAL FRANCIS UNIVERSITY OF** — This university is situated in the city of that name, the capital of the province of Galicia, Austria, and is the younger of the two Galician universities, the older being Krakow. It had its origin in a Jesuit institution, established in the second half of the seventeenth century, the original charter dating from the year 1661. It was not until almost a century later, however, that this charter received the Papal sanction, the confirmation of King August III in 1758 being followed a year later by a bull of Pope Clement XIII. In 1784 the Jesuit college was transformed into a state institution by Emperor Joseph II, the language of instruction from this time on until 1824 being Latin. In 1805 the institution was again reorganized and given the rank of a lyceum, and eleven years later it was raised by Francis I to the dignity of a university of three faculties, theology (Catholic), philosophy, and law and political science, the medical faculty not having been added until 1891. The faculty of philosophy includes a department of pharmacy. From 1824 until 1871 German was employed as the language of instruction in the faculty of philosophy and in the majority of courses given under the faculty of law. Since that time, however, a number of changes have been instituted, and at the present day Polish holds complete sway. The library of the university contains about 220,000 volumes, over 900 manuscripts, and almost 12,000 coins and medals. The annual budget amounts to approximately \$275,000. In the winter semester of 1910-1911 there were 4704 students in attendance, of whom the majority were registered in the faculty of law.

Lemberg also contains a technical school, founded in 1884, in which the language of instruction is Polish and which was attended by 1745 students in 1910-1911, a college of veterinary medicine, founded in 1881, which grants the degree of Doctor of Veterinary Medicine, and the Ossolinski National Institute, which contains a library of 130,000 volumes, especially valuable for Polish history and literature, and almost 5000 manuscripts, over 2000 maps, 22,000 coins and medals, autographs, engravings, paintings, etc.

## LESSING, GOTTHOLD EPHRAIM

**LENOX COLLEGE, HOPKINTON, IA.** — A coeducational institution opened in 1859; it is under the care of the Presbyterian Synod of Iowa. There are maintained an academy, college of liberal arts, a school for teachers, and schools of commerce, agriculture, music, expression, and art. Two courses are offered, leading respectively to the degrees of A B and B.S. The enrollment in 1910-1911 was 138 students. The faculty numbers fifteen members.

**LEONARD AND GERTRUDE** — The title of Pestalozzi's epoch-making educational romance. See PESTALOZZI.

**LEONARDO OF PISA** — See FIBONACCI.

**LESSING, GOTTHOLD EPHRAIM** (1729-1781) — This German critic, dramatist, and philosopher is one of the very few men who, without becoming a teacher or a writer of educational books, have won permanent places for themselves in education. He was born at Kamentz, Saxony, and died at Wolfenbittel, Brunswick. He was the son of a Protestant minister, and was destined for the Church. He early showed ability as a student, but the attempts to give him university training, first at Leipzig and then for medicine at Wittenberg, resulted in failures, because of his growing fondness for the drama. He then decided to make literature his profession. In spite of financial limitations, many disappointments, and frequent change of residence, he became the best expression of the German *Aufklärung*, and gave the Leibnitz-Wolffian philosophy a new impulse by adding a poetical element and by turning it into effective channels of individual culture. He may be credited with having created the art of modern literary criticism, and awakened the national, literary spirit of modern Germany. His greatest work is *Laokoon, or the Limits of the Plastic Arts and Poetry* (1766). His best dramatic writing is *Minna von Barnhelm* (1767), which led the way for a distinctive German literary expression, and in more recent years has been serviceable in American schools as a reading text for students of German. While director of the national theater in Hamburg, he so presented the traits of dramatic art and so struggled for freedom from French standards in the Hamburg dramatics (1767-1769) as to arouse critical opposition to his æsthetic ideals. After being compelled to cease the religious controversy in his later years occasioned by his anonymous publication of Reimarus's *Wolfenbittel Fragments*, he employed the drama as a means of expressing his passion for freedom of thought, writing *Nathan the Wise* (1778-1779).

Lessing's influence on education was in large part directly due to his manner of conceiving and interpreting the problem of the spiritual

nature of man from the pedagogical point of view. The philosophical and religious issues of his age received profound modification because of the singular aid he brought to them from his large and bold conception of education. Education puts nothing foreign into a person, but only anticipates what each one could secure for himself. Its results cannot be attained at once, but depend upon irregular stages of development. It assumes the possibility of the moral perfection of man, which includes the ideals of rationality and freedom. These cannot be obtained by a single individual nor by a single age. Education uses for purposes of discipline and instruction the material that can be gathered only in experience. The most important problem in education is, not an arousing of emotion, but a formation of the will through a construction of a rational field of thought. As each individual appears at a certain level in the total development of humanity, he must be trained to look to the past, and not forget the task of advancing the future. Education is the orderly arrangement of the development of working ability in the pupil in conjunction with the adapted order of the topics of instruction.

God leads the human race in a way, not analogous to, but identical with, the process of the education of the individual. Tracing this educational parallelism between the race and the individual is the task of Lessing's briefest, and one of his most important books, the *Education of the Human Race* (1780). Religious dogmas he revised in the light of universal development. Religion and revelation go together, for the history of positive religion is merely the divine education of humanity. Man's actions are guided at first by instinct, reason slowly acquires direction of the will, until finally freedom appears. Education is the natural and normal process whose methods and ideals are applicable equally to the individual and to the race. The recapitulation theories which play an important rôle in the educational thinking of the nineteenth century had their sane and vigorous start in Lessing's keen analysis of the educational process and the application thereof to the phenomena of reason, religion, history, and society. E. F. B.

**LESSON PERIOD.** — See *SCHOOL MANAGEMENT*.

**LESSON PLANS** — It is the practice of supervisors in training or practice schools to demand plans of the lessons to be taught by student-teachers or apprentices. These are written and submitted to the supervisor in advance for criticism. They vary somewhat in form, but in general they agree in calling for a statement of the special aims of the lesson, the subject matter selected for the purpose, and the pedagogical methods employed at each step of the procedure. The subject matter and the teaching procedure are frequently stated in parallel columns so as to indicate their relation in time sequence. At first only a single lesson is included within the plan, later several lessons may be included within the unit of a larger topic, thus weekly, monthly, and term plans of teaching procedure may come within a single plan. In certain schools where close supervision of teaching is provided, lesson plans extending over the wider units of time may be required of teachers in regular service.

The lesson plan is useful in assisting the young teacher to organize his work, in giving the supervisor some means of preventing avoidable mistakes and crudities, and in saving the teacher in the classroom from that diffuseness which is likely to arise in adjusting the process of instruction to the children's interests, errors, questions, and doubts. In so far as the lesson plan fixes a general procedure in the mind of the teacher and leaves the specific adaptations to be made in the classroom, it is a useful device. Overinsistence upon the writing and following of lesson plans may make the instruction formal and rigid, depriving it of that flexibility and spontaneity which are requisite in using the full resources of teacher and pupils. The application of the lesson plan in any very detailed way to the supervision of teachers in service is a doubtful procedure. A trained and experienced teacher charged with the full responsibility of class control and instruction has neither the need nor the energy for the preparation of detailed written plans. The teaching art is so much a matter of opportune presentation and interpretation of experience that a clear knowledge of the purposes of the school, a scholarly command of subject matter, and a command over the fundamental principles of teaching once acquired are about all that the professionally trained and experienced teacher requires by way of preparation. The rest is a matter of insight and inventiveness in the face of classroom situations. Frequent self-criticism and supervisory aid provide for the proper growth required from year to year. H. S.

**LESSON, TYPES OF** — The term "lesson" is applied to the unit of teaching activity which occurs within the time assigned to a class period in the school schedule. For the purposes of administration these lessons are designated in terms of the subject matter treated, *e g* geography, reading, civics, or geometry lessons. For the pedagogical purposes of teaching and supervision, they are named after the dominant type of teaching method employed in the lesson, *e g* drill, review, examination, recitation, developmental lessons. H S

See TEACHING, TYPES OF

**LETTER METHOD** — In the teaching of reading or spelling, any method which utilizes the letter as a unit of analysis or synthesis in the treatment of the structure or sound of words is a "letter" method of teaching. Thus (1) teaching spelling or reading by spelling the letters, the alphabetic method (2) by sounding the letters, the phonetic-alphabetic method, and (3) by marking the letters and then sounding them, the diacritical method, are all species of the "letter" method. H S

**LETTER-WRITING** — See EPISTOLÆ

**LETTERS AND ARMS** — The famous controversy as to the precedence of physical prowess in war, or the mental triumphs of learning and knowledge was part of the larger dispute between noble birth and personal merit. The humanists appealed to Cicero's dictum, *cedant arma togæ*. The Ingenious Gentleman, Don Quixote (pt 1, ch xxxviii Ormsby's translation, pp 212 *et seqq*), compares the student and the soldier, a favorite comparison, when the days of chivalry ripened into the Renaissance. Letters say that arms cannot be maintained without the laws laid down in military writers. Arms can equally reply that without them laws laid down in letters cannot be maintained, for states are dependent for their very existence upon their armies.

Judged by difficulties of attainment, eminence in letters may require "time, watching, hunger, nakedness, headaches, indigestions, etc." But to become a good soldier "costs a man all the student suffers, and in an incomparably higher degree, for at every step he runs the risk of losing his life." Don Quixote makes an attack on "engines of artillery" and assigns their invention to hell, for making it easy "for a base and cowardly arm to take the life of a gallant gentleman." It is clear that Don Quixote awards the palm to the soldier over the student. Mr H E Watts (*Don Quixote*, Vol II p 211 n) quotes from

Bowles the name of a work entitled *Discorso sopra la Lite delle Armie et delle Lettere* (Firenze, 1580) by Francesco Bocchi, who, like Don Quixote, decides in favor of arms. He also names a treatise entitled *Pro Equitate contra Literas Declamatio* by a Spaniard, Juan Angel González, published at Valencia in 1549. In 1576 Louis Leroy wrote a book contrasting modern and ancient knowledge, and entitles it the *Interchangeable Course or Variety of Things in the whole World, and the Concurrence of Arms and Learning, through the first and famous Nations* (translated into English by Robert Ashley in 1599). Leroy has no hesitation in awarding the palm to learning, and this was the position taken up in most of the books as the Renaissance spirit gained sway. The discussion naturally plays an important part in the books on the education of gentlemen and nobles (*q v*). Thus, Ascham (*q v*) in his *Schoolmaster* (1570) describes the whole tendency of Castiglione's *Cortegiano* (*q v*), "To join learning with comely exercises Conte Baldesar Castiglione doth trimly teach."

In 1595 William Jones translated the *Nennio or Treatise of Nobility* written by John Baptist Nenna of Bari, who was both a doctor and a knight. The author hesitates to say which is more excellent and noble, "that which doctors purchase by their learning or knights by arms." In 1598 J Keper translated the *Courtiers Academie* of Count Hannibal Romei (first published in Italian at Ferrara in 1588). In this book Romei devotes a chapter to the subject of the "Precedence of Letters and Arms, two most principall Faculties" — and decides in favour of military art, which according to the author has all the characteristics of the liberal arts, *viz* "material subject, end, and the instrument which to the end conduceth."

**LEVELS OF DEVELOPMENT** — See GROWTH, CHILD PSYCHOLOGY; ADOLESCENCE AND YOUTH; also PLATEAU.

**LEVERETT, JOHN** (1662 – 1724). — Seventh president of Harvard College, educated at the Boston Latin School and Harvard College, graduating in 1680. He engaged first in the ministry and later in political life. He was speaker of the House in the Massachusetts Legislature and judge of the superior court of that commonwealth. He was president of Harvard College from 1708 to 1724.

W. S. M

**LEWIS, DIO** (1823 – 1886) — Author of a system of gymnastics, graduated from the Harvard Medical College (1845). He was teacher in the public schools and lecturer on physiology and physical training from 1837 to

1861, when he founded in Boston a normal school for the training of teachers of gymnastics. Author of *New Gymnastic System* (1862), and many essays on physical training.

W S M.

**LEWIS, SAMUEL** (1799 - 1854). — First state superintendent of schools of Ohio. He attended the public schools and engaged in teaching. He did pioneer work in Ohio, and, as state superintendent (1837-1843), he investigated the educational conditions of the state on horseback, visiting over three hundred schools during his first year in office. He secured the enactment of a state school fund, the privilege of loans to poor districts for the erection of schoolhouses, and the publication of a state educational journal, *Ohio School Director*, of which he was the first editor. He was one of the organizers of the Western Literary Institute (*q v*), and continued a member of the Ohio State Board of Education from the expiration of his term of office to the time of his death.

**LEYDEN, UNIVERSITY OF, HOLLAND.**

— One of the four royal universities of Holland, founded in 1575 to commemorate the successful end of the siege of the town by the Spaniards. Given the choice by William I of immunity from taxation or the permission to found the university, the citizens preferred to establish a "free public school and university." The institution was housed at first in the Convent of the White Nuns, part of which was rebuilt by the municipality in 1618 and is still used. "The university at once became the center and rallying point of Protestant students, Huguenots from France and Puritans from England, and attained a great reputation in Europe through the eminence of its scholars and teachers, among whom was Joseph Scaliger, Lipsius, Vossius, Hensius, Grotius, Salmasius, Boerhave, Arminius, etc. In 1807 the Leyden became a royal university of Holland, but in the Napoleonic reconstruction of 1811 it was turned into an academy of the University of France, only to be restored to its earlier position in 1815. Its present organization goes back to the Law for Higher Instruction of 1876. There are now five faculties: law, medicine, science, letters, and theology. A remarkable feature of this university, as of other Dutch universities, is the extent of academic freedom enjoyed by teachers and students. The enrollment in 1910-1911 was 1195.

**LEYS SCHOOL, CAMBRIDGE, ENGLAND** — See GRAMMAR SCHOOLS, ENGLISH; COLLEGE, COLLEGES, ENGLISH, PUBLIC SCHOOLS.

**LIBANIUS** — A distinguished Greek sophist (*i e* teacher of rhetoric and oratory) of Antioch in the fourth century A D. He was born in 314, of one of the respected families of Antioch. His father dying when he was eleven years old, he was left to the care of his mother and her two brothers, who undertook personally to direct his education. Until he was fifteen he displayed little liking for books, but he was then seized with a passionate desire for learning, which led him in the end to seek the sophist's life. At the age of twenty-two he went to Athens, and spent four years at the university there. He opened his first school at Constantinople, where he taught with great success, but, being compelled by the intrigues of rival sophists to leave the city, he retired, first to Nicæa, then to Nicomedia. At Nicomedia he taught five years, at the end of which time he was recalled to Constantinople. In 354 he removed to Antioch. There he at first set up a private school, but soon received an official appointment, with a salary from the state. He taught at Antioch until about 394, which was probably the year of his death.

Libanius's position as "sophist of Antioch" (the title given him by John Chrysostom) was one of great importance in the city, and carried with it much personal influence. The school of which he was head consisted of himself, at least four "rhetors" (probably teachers of the more elementary or technical, or of the more practical, as distinguished from the more literary, part of oratory), one or more "grammarians," or teachers of literature, and, at one time, a teacher of Latin, and possibly a teacher of law. Either by appointment or through his personal influence, he acted as Director of the whole school and university system of Antioch, subject, of course, to the direction of the municipal council and the emperor. He was the mouthpiece of council and teachers in their dealings with each other, and at times made the selection of new teachers, and determined, in some degree, the amounts of their salaries. Libanius's pupils came from all parts of Asia, as well as from other parts of the Greek world. They went forth from his school into nearly every walk of life. Though firm in his adherence to the old faith, he numbered among his friends pagans and Christians alike. He had great influence with all ranks of officials, and was ever ready to advance the

interests of his fellow citizens and of his city. He was admitted to the intimacy of the Emperor Julian, by whom he was greatly admired, and whose untimely death he bitterly lamented.

Libanius has left us a considerable body of writings. They are sixty-four speeches, including an autobiography, about fifty declamations, a large mass of rhetorical and school exercises, such as descriptions, character sketches, narratives, together with arguments to the speeches of Demosthenes, and over fifteen hundred letters, addressed to all classes and kinds of men. The speeches are on topics and events of the day, and they abound in autobiographi-

cal notices and in references to the life of the times. A like interest attaches to the letters, which are invaluable for a depiction of Libanius's character and for information about the men and the manners of the day.

The best edition of Libanius is that of Richard Forster, which is still in course of publication and of which six volumes have been published to date (1903-1911, Teubner, Leipzig).

# A CYCLOPEDIA OF EDUCATION (4)

**LIBERAL ARTS** — A term used in contradistinction to the fine arts on the one hand and the technical and practical arts on the other (for the former, see **ART IN THE SCHOOLS**, etc., for the latter see **INDUSTRIAL EDUCATION** and **TECHNICAL EDUCATION**) The liberal arts have constituted from the time of the Greeks the curriculum of secondary and higher schools. The function of the liberal arts in education is discussed in the aspects in **ART IN EDUCATION**, **COURSE OF STUDY**, **THEORY OF**, and **LIBERAL EDUCATION**. The other aspects of greatest educational interest of the liberal arts concerns their organization into a curriculum and the development of scholastic degrees in connection with them.

During the Middle Ages the liberal arts were organized into a distinctive curriculum, including seven of the arts only. The "Seven Liberal Arts" included substantially all learning. These subjects comprise grammar, rhetoric, and dialectic, also called the trivium, and arithmetic, geometry, astronomy, and music, also called the quadrivium. The distinction between the lower and higher groups of subjects goes back to Plato, who found in music and gymnastics, the traditional Greek curriculum, sufficient material for the earliest stages of education, but organized an advanced stage in which the appropriate subjects were arithmetic, geometry, music, and astronomy. Dialectic or philosophy was recognized as a yet higher stage, appropriate only for the intellectual class. Aristotle's treatment of the curriculum is incomplete, and does not include discussion of the advanced stages. He adds reading, writing, and drawing to the traditional music and gymnastics of the old Greek curriculum. It is evident that he would add some study of the natural sciences to the advanced subjects. These were called the liberal subjects. The sophists and rhetors laid especial emphasis on the three introductory subjects, grammar, rhetoric, and dialectic, using dialectic to indicate logic, now scientifically formulated by Aristotle and no longer the general philosophical study of Plato. The Romans borrowed the Greek organization of learning, making it more systematic. M. T. Varro, a contemporary of Cicero and Cæsar, wrote a treatise, now lost, on *The Nine Liberal Disciplines*. To the seven of later authority were added medicine and architecture. Quintilian and Seneca wrote on these subjects,

but assigned no definite number of studies to an approved curriculum. During the fourth century Martianus Capella (*qv*) wrote the *Marriage of Philology and Mercury*, in which for the first time the arts appear authoritatively as seven. The arts represent the bridesmaids in a heavenly wedding, and on the ground of their mundane characters medicine and architecture are omitted. At about the same period Augustine wrote a treatise on six of the liberal arts, omitting astronomy and possibly other subjects because of other work and interests.

Probably Cassiodorus (*qv*) (480-575) was the first to assign the limit of seven as authoritative. This he did in his treatise *De Artibus et Disciplinis Liberalium Literarum*, which formed a companion piece to a work on sacred literature, both written for his monastic brethren. Here the seven pillars of the temple of Wisdom referred to in Proverbs (ix, 1) is given as conclusive evidence of the fixity of the curriculum. Thus, as the Roman had absorbed the Greek, so the Christian accepts the Roman organization of learning. Isidore of Seville (*qv*), who comes shortly after, limits the subjects to seven and uses the terms *trivium* and *quadrivium*. Succeeding medieval writers indicate that the terms are fixed. Many of the great monastic leaders, later the schoolmen, and in fact all who wrote on education, give treatises on all or some of the seven liberal arts. Especially is this true of the earlier periods, with such as Alcuin (*qv*), Rabanus Maurus (*qv*), with whom as with the later schoolmen, interest was more intense in philosophical and dialectic discussions. Painting, sculpture, and engraving add their testimony to the universality of this organization of learning even after the Renaissance brought that wider interest in knowledge which finally resulted in the overthrow of the fixed restricted conception of the limits and divisions of learning. Yet it must not be understood that the content of these various subjects was the same as in modern times. For the most part the extent of these subjects was far broader, even if the content of some of them was not so profound.

**Grammar.** — This subject included the study of literature as well as that of the grammatical structure of languages. Quintilian says of the subject (I, 4) "This profession, distinguished, as it is, into two parts, the art of speaking cor-

rectly, and the illustration of the poets, carries more beneath the surface than it shows on its front." The same conception prevailed with the later Greeks Dionysius Thrax (c 166 B.C.) divided grammar into six parts: "(1) trained reading, with due regard to prosody, (2) exposition, according to poetic figures, (3) ready statement of dialectic peculiarities and illusions; (4) discovery of etymologies, (5) accurate account of analogies, (6) criticism of poetical productions, which is the noblest part of the grammatical art." The medieval definitions are quite as broad. Isidore defines grammar as "the science of correct speaking and of the sources and foundations of literature"; Rabanus Maurus, as "the science of interpreting the poets and histories and the method of correct writing and speaking."

Grammar was thus equivalent to our term "language and literature," and as such monopolized the attention of students during the early half of the Middle Ages and formed a broad foundation for the elaborated curriculum of the later Middle Ages.

The purpose of grammatical instruction was first, then, to give the student a working knowledge of the Latin language. To do this to those who had no vernacular training, since Latin had now become a "dead" language, or at least a foreign tongue, with few books for the students, was a new task. As aids to this new educational problem a great variety of texts were produced. Donatus (*q.v.*) still furnished the foundation. But a number of compilations of proverbs, fables, dialogues, or colloquies were produced to give a reader command through inductive methods. The so-called Cato's *Distichs* (*q.v.*), a series of 143 couplets or moral maxims, formed the most popular. Memorizing of these gave a vocabulary and a working knowledge. Other grammars supplemented those of Donatus and the more elaborate one of Priscian. (See LATIN LANGUAGE.) Some of these were component parts of encyclopedic works on the Seven Liberal Arts, such as those of Capella, Cassiodorus, Augustine, Isidore of Seville, Alcuin, and Rabanus Maurus. Each century, however, produced a number of independent treatises on Latin grammar, most of them introductory texts, more appropriate to the task of introducing the pupil into a foreign tongue in an age when general culture was at a minimum and books and other ordinary means of instruction were scarce. The most noted of all these texts was the *Doctrinale* of Alexander de Villedieu (*q.v.*), written in 1199. Its most striking characteristic was that it was written entirely in verse. When the method of introductory grammatical study was wholly by memorizing, such a text had great advantages. It became very popular, almost replacing the other text and rivaling Donatus. The *Doctrinale* embodied many of the changes which the language had undergone in the period intervening since

Priscian's work, incorporated a vocabulary more necessary to the Church, and adopted methods more in harmony with the dominant dialectic interests. Other popular texts, such as Bethune's *Græcismus*, were also in verse. In addition to the grammars, numerous vocabularies appeared in the various vernaculars to assist the grammar student.

The extent to which the study of grammar introduced to a knowledge of literature is much disputed. Priscian quotes the *Æneid* of Vergil more than 700 times in his grammar. Aristophanes, Aristotle, Julius Cæsar, Cicero, Demosthenes, Herodotus, Homer, Horace, Juvenal, Lucretius, Ovid, Sallust, Terence, and other writers are also quoted, some of them more than a hundred times. Naturally none of the later texts contained anything like this amount of literary material. But a thorough study of Priscian would give a fair introduction to some of the Latin authors. To what extent the authors themselves were read is even a more disputed question. Whatever the facts may be, it is evident from recent investigation, that the old opinion concerning the ignorance of the Middle Ages must be revised to a very considerable degree. Theodulphus, Bishop of Orleans and successor of Alcuin, states that he actually taught from Vergil, Ovid, Pompeius, Sedulius, Rutilius, Arator, Fortunatus, Juvenius, Prudentius. A century later Walter von Spier comprised in his grammatical studies Vergil, the Latin Homer, Horace, Persius, Juvenal, Statius, Terence, Lactantius, Boethius, and Constantine. Such lists could be extended indefinitely. Students from various centuries have left testimony as to literary activities quite as extensive. It is but natural that the Christian authors should predominate. But a knowledge of classic literature was not extinct.

**Rhetoric** — This formed the most important subject of study in Roman education, but during the Middle Ages it was the least important of the subjects of the trivium. Rhetorical training was essential in a society where political interests were dominant, but it had little significance in the training of the clergy or the men of public affairs during the Middle Ages, for church services called for little or no oratorical power, and public affairs developed no learned or trained class aside from the clergy. Rabanus Maurus states in his treatise on rhetoric, "It is sufficient if youths give some attention to the study of rhetoric. Even then not all who expect to enter the priesthood, but only those who are not as yet obliged to devote their time to pursuits of greater usefulness, should study the subject. At any rate one who wishes to acquire the art of eloquence can do so more advantageously by reading and hearing great orators than by studying the rules of rhetoric." But there was a general need in an uncultured society for a professional class that could write and compose the various docu-

ments necessary in the complicated ecclesiastical, legal, and political life of the times

The study of rhetoric then became directed to two objects: training in composing letters to various people in authority and in constructing various documents such as contracts, wills, decrees, deeds, commendations, immunities, or records of any kind. The first was known as *Epistolæ*, the second as *Dictamen* (*qv*). While the various encyclopedic texts, based largely on the old Roman writers, such as those of Cassiodorus, Capella, Isidore, and Rabanus Maurus, continued to be used to some extent, far more popular were the various textbooks prepared on *Epistolæ* and *Dictamen*. The former texts dealt in a formal way with the superscription, salutation, exordium, narration, petition, conclusion, and subscription; the latter contain models for the various kinds of documents needed in temporal and ecclesiastical affairs and in common life, such as privileges, commissions, citations, donations, petitions, exemptions, visitations, etc. Many manuscripts left are the dictation of teachers or the exercise work of scholars, and it is now thought that frequent instances of this character were but recently held to be pious forgeries of designing ecclesiastics. With the founding of the universities the study of rhetoric merged into the study of Roman law, into which the *Dictamen* developed. In some universities, courses in the *Ars epistolandi* were also given.

**Logic** — This subject was identical with dialectic, but though closely bound up with philosophy and metaphysics, did not include them as a school subject. Especially during the early Middle Ages were metaphysical and philosophical interests quite foreign. With the development of theological interests in the eleventh century, metaphysical distinctions and philosophical doctrines became of great importance; but it was only with the development of the universities and the recovery of the work of Aristotle that philosophy was added as a distinct part of the curriculum. The writings of Boethius (*qv*) were the sources from which the early Middle Ages drew its knowledge of logic. While with Boethius the metaphysical and philosophical implication and the relation of logic receive the greatest attention, it was his formal logic that was drawn upon for textbook purposes. Similarly Cassiodorus, Capella, Isidore, and Alcuin furnished in their encyclopedic treatises text for common use. But these again dealt almost exclusively with formal logic. With the rise of the theological discussion following Rabanus Maurus and Scotus Erigena, logic became of transcendental importance, was generally mentioned second in the trivial studies, and in reality replaced grammar and its inclusive though superficial study of literature.

While from now to the close of the Middle Ages logic was the subject of greatest importance because it became bound up with all

other aspects of study and all phases of intellectual interest, yet as one of the Seven Liberal Arts studied in the schools and the universities it was formal logic alone. Logical metaphysics was reserved as a part and function of theology. Both during and preceding the university period numerous brief school texts on formal logic appeared. By far the most famous of these was the one by Petrus Hispanus (d. 1277), which was very generally used for 300 years.

**Arithmetic** — The church was interested in the study of arithmetic, astronomy, and music, the major portion of the quadrivium, as well as in the study of the trivium. The standard encyclopedic texts of Boethius, Cassiodorus, Isidore, Alcuin, Rabanus were the basis for the study of arithmetic. While following this period numerous treatises and textbooks on arithmetic were produced, there was really no creative work and no advance made in the subject until the thirteenth century. At this time the algoristic or Arabic notation came into general use. The chief practical arithmetical interest was in the calculation of Easter. The works of Bede and of Rabanus Maurus were the chief treatises. The ordinary monk or priest, by the use of Bede's rules, could compute Easter with a knowledge of the four fundamental processes. Numerous church synods required this much arithmetical knowledge of all priests, and after the time of Charlemagne this knowledge was fairly general. To such an extent did the computation of Easter, and one other practical problem — the use of the abacus (*qv*) — make up the whole of arithmetic, that the ordinary term for the subject was *computus*. But the older texts, based upon Boethius, hardly touched the practical aspect of the subject. They scarcely have a reference to a rule of operation. They are devoted for the most part to a classification of numbers, a study of their properties, mystical, symbolical, and otherwise. Bede and Rabanus depart from this, later minor textbook rules follow them, and in the last centuries of the Middle Ages a great variety of texts appeared. The advance in arithmetic dates from Gerbert (*qv*), later Pope Sylvester, to whom is attributed by some the introduction of the Arabic notation. Without question he introduced the columnal computation and the methods of fundamental operation substantially as they are to-day. The introduction of the Arabic notation was very gradual, and its general acceptance was the work of the thirteenth and following centuries. Boethius persisted as a text into the sixteenth century. From the opening of the thirteenth century, arithmetic found new utilization in commerce and industry, and there were two distinct types of arithmetical texts corresponding to the two types of mathematical interests, — the theoretical and the practical. In fact, these aspects appeared as two distinct subjects, *arithmetica* and *algo-*

**rismus.** The former was encouraged in the universities, though some, such as Paris, gave little or no attention to arithmetic. In some institutions, as Vienna and Leipzig, both subjects received attention (See ARITHMETIC; ALGORISM; COMPUTUS; NOTATION).

**Geometry.** — The course followed by geometry was much the same as in the case of arithmetic. In the early third of the Middle Ages it was studied exclusively from the encyclopedic texts, though the treatise of Boethius seems to have been unknown. The scope of the subject, however, was that indicated by the etymological significance of the term. It corresponded to modern ideas of geography plus the rudiments of surveying. It was based on Pliny rather than upon Euclid. Capella adds some treatment of lines, circles, triangles, chiefly of their symbolic meaning. Rabanus writes *On the Universe* as a treatise in geometry. With Gerbert in the tenth century, a knowledge of Boethius's summary of Euclid was again brought to light. In extent it was limited to the first four books of Euclid, with full demonstrations of only three or four propositions. From the thirteenth century on, beginning with translations from Arabian sources, the subject rapidly expanded.

**Astronomy.** — In the quadrivium this was the most popular as well as the most practical subject. Its practical use in the calculation of the calendar and in the construction of the sundial gave it a greater everyday value than arithmetic, with which it was closely bound up. Its general aspect was astrology, which was of far more practical concern to the common man than modern mathematical astronomy. In fact, astrology was related most intimately to every aspect of everyday life, and as such was a study of utmost practical concern. Whether astronomy or astrology, it was the same symbolical and mystical interpretation of phenomena that so characterized all of the theoretical study of that period. In addition to the symbolical material, the ordinary texts included the elements of mathematical geography to about the same extent that a modern school geography does, making allowance for the difference in actual scientific knowledge. Such texts were those of the encyclopedists Capella, Cassiodorus, Isidore, Alcuin, and Rabanus. Bede's work was more comprehensive. In the early university period translations of Ptolemy and of Aristotle *On the Heavens* were introduced and widely used. Elementary texts, especially that of the English monk, Sacrobosco (thirteenth century), appeared and were widely used. The general interests in and the character of teaching of astronomy in the later Middle Ages were such as to afford an excellent foundation for the rapid advance made in the Renaissance period. (See ASTROLOGY; ASTRONOMY.)

**Music** — As one of the Seven Liberal Arts, music had little in common with our

modern idea of music. It consisted of the mathematical study of music, together with mystical and symbolic study of numbers after the Pythagorean ideas. It concerned itself neither with singing nor with ability to perform on an instrument. There was some practical study of music, made necessary by the church services; but this was not a liberal art, and the development of secular and folk music did not begin until late in the medieval period. As long as the Greek ideas of music prevailed, — and this was for the greater part of the Middle Ages, — there was no escape from these conditions. Boethius was the standard text, as he continued to be in the universities down into late modern times. Cassiodorus, Isidore, and other encyclopedic texts were used, but they were for the most part condensations of Boethius. Music in this sense was a part of the regular university course, and also appeared very generally in monastic and cathedral schools throughout the Middle Ages.

The later historical aspect of the arts curriculum is considered in the articles on each of the subjects mentioned; UNIVERSITIES; COLLEGE, COLLEGE, AMERICAN, incidentally in the articles on DEGREES and related topics. See also the cross references given under MIDDLE AGES, EDUCATION IN.

**LIBERAL EDUCATION** — The conception of liberal education dates from Aristotle. He distinguished sharply between a liberal education, an end in itself, and a mechanical or professional training, a means for practical ends beyond itself. The chief traits of a liberal education were its association with leisure and its exclusive connection with the faculty of knowing. These two traits were necessarily combined with each other. Slaves, serfs, mechanics, tradesmen, were too much occupied with practical matters to have the leisure requisite for devotion to knowing for its own sake. Only a leisure class was in a situation to devote itself to the cultivation of the mind for the sake of the mind. Even in theoretical matters, however, excessive assiduity evinced an illiberal spirit. The chief material of a liberal education was music (in the Greek sense). The question how far practice was necessary was decided by applying the criterion suggested

above. If skill in doing became the chief end, the study was illiberal. Practice for the sake of doing should be relegated to the servile, unfree class of artisans. In a liberal education that amount of practice should be permitted which would promote the understanding and enjoyment of the arts as practiced by others.

The distinction between liberal and servile education was thus based by Aristotle upon the distinction of classes upon which Greek society was founded. Practice and education for practice were essentially illiberal because pursued by persons who were not free themselves or, who if legally free, were so given up to the narrow ends of money making, etc., as to have no interest in the exercise of the knowing faculties for their own sake. This exercise was the appropriate and congenial function for those whose social station relieved them from all menial preoccupations.

The distinction between the free character of knowing and the sub-servient character of doing which underlay the Aristotelian definition of a liberal education was also associated with several points in his metaphysical and ethical system. Pure knowing, concerned only with the rational relations of immaterial forms, was, according to Aristotle, the highest thing in the universe. It was the final cause of the existence of nature, the supreme end and good. It defined the nature of God as pure activity. It dealt with the reason, the explanation of all else, and was complete in itself — just as a syllogism is self-inclosed, needing no help from outside. In contrast, doing or practice sprang from appetites, which are bodily, not ideal — expressed needs, lack, incompleteness, imperfection, and in general was due to man's share in the animal, not the divine nature. The highest, the freest, or most liberal of all pursuits was a theoretical contemplation and inquiry which were *supra-civic*.

Aristotle's distinction became basic in all later definitions and classifications of education. It took specific effect in the conception of the seven liberal arts (*q v*). His assertion of the supremacy and divinity of the purely theoretical life was employed in the middle ages to justify theology as the supreme study, and to place the monastic life above not only secular careers but above that of the parish clergy — the latter being devoted to necessary practices and not to the exclusive cultivation of divine knowledge.

At the time of the revival of learning, however, the domination of theology and allied concerns was taken as a symptom of a professional education, that preparing for the clergy. Liberal education was identified with the humanistic studies, a knowledge of classic antiquity and the Greek and Latin literatures. Although the older classification of the seven liberal arts survived, these arts — such as grammar, rhetoric, logic — were identified, not with "sacred" grammar and rhetoric

and with the logic which was a handmaiden of theology, but with that of classic literatures. However, the interest in the content of these literatures tended, while reviving the idea of liberal education, to relegate its conventional divisions to the background.

In the eighteenth century the rise of natural science began to disturb the now orthodox identification of the liberal with the ancient languages. Pure mathematics was unambiguously taken in the fold, the other sciences were left as doubtful claimants. In the nineteenth century the further development of literature and philosophy in the vernacular tongues of Europe gave the living languages a claim for recognition as elements in liberal education. The growth of history and the social disciplines perturbed the content of the idea still further. Liberal education had claimed to be the peculiar representative of man as man, of human interests as such; and history, anthropology, political economy, and sociology seemed to concern themselves with humanity even more directly than did the classic literatures.

As a consequence of such causes, practically all attempt to define a liberal education by some principle of content has been given up, though it is still generally felt that Greek, Latin, and mathematics, at least from algebra through calculus, are peculiarly liberal in character. The attempt is now made to define it from the standpoint of aim, or of a peculiar, if intangible, influence it exercises upon those devoted to it. This end and effect are more easily stated from the negative side than from the positive side. Some would call it scholarship and would say that higher education, as distinctly representing the liberal interest in education, should be given to the promotion of scholarship. Among those representing this idea there is, however, a marked difference of attitude. Some would include research and discovery in the province of scholarship, while others would exclude them as specialized and technical. Many deny the claim of scholarship to represent the cause of liberal education and would substitute a specific refining and ennobling of the mind known as culture. However, the status of various subjects with respect to their power to bestow culture is involved in much uncertainty and polemic discussion. Negatively, the conventional idea of a liberal education is more easily made out. It excludes education designed to prepare one for any special calling, particularly if this calling is closely associated with money making, or if preparation for it involves much manual manipulation and dexterity — such as the laboratory pursuits of a technological education. Latterly, it has been held by professed upholders of the cause of liberal education that it is opposed to education for social service. This notion, however, is mainly an American innovation. Historically, the chief pursuit of the leisure class has been statecraft and diplomacy. One of the leading marks of lib-

eral studies was that it prepared men for managing the state, including the lower classes. In the United States, with the development of democracy, the notion of a special ruling class with a special education fitting it for social control has disappeared. Accordingly education for social service is no longer education for directing the affairs of other people, but for contributing to their happiness and well-being. Such a conception would lie in the physician and the engineer. Consequently it is too broad for the purposes of the traditional notion of liberal education.

The fact is that in a society which frankly bases its constitution upon class distinctions, it is comparatively easy to assign a distinct content and a distinct purpose to liberal education. With the growth of social studies, of the democratic ideal, and the increased application of the best scientific intelligence to the conduct of practical affairs, it becomes increasingly difficult to do so. Liberal education becomes a name for the sort of education that every member of the community should have: the education that will liberate his capacities and thereby contribute both to his own happiness and his social usefulness. It has value as a limiting concept to criticize various educational schemes. Thus an education in Latin and Greek may be quite illiberal if pursued by methods which restrict the play of the imagination and the sympathies, and bind down mental appreciations to one limited sphere. The same is obviously the case with education for law, medicine, engineering, or the clergy. In short a liberal education is one that liberalizes. Theoretically any type of education may do this. As matter of fact, all of them fall much short of accomplishing it, some in one respect and some in another. In so far they fall short of being an education in any worthy sense of the word. J D

See ACTIVITY; CULTURE, HUMANISM, LIBERAL ARTS.

**LIBERIA, EDUCATION IN** — Liberia is an independent negro republic under the control of black men, and has maintained its sovereignty for sixty-four years. It extends 350 miles along the coast of West Africa and 200 miles into the interior, and possesses thirteen ports of entry. The population is above one and a half million, of whom 25,000 are emigrants from the United States and their descendants. Planted by the American Colonization Society in 1817, Liberia declared its independence in 1847. In language and institutions the leading people are strongly attached to the United States.

The American-Liberians exercise ever increasing authority over the aboriginal tribes, which, however, are dominated by several native chiefs. A strip of land twenty to eighty miles broad extending along the Atlantic coast is effectively administered by the govern-

ment, which is modeled on that of the United States. The coast region is divided into four counties, Bassa, Sino, and Maryland, each under a government superintendent, and Montserrado, which is subdivided into four districts, each under a superintendent. This local organization has facilitated the progress of public education. The government system is based upon an act of 1869 providing for the maintenance of at least one public school in every settlement and township in each county. The act called for an annual appropriation of one thousand dollars from each county treasury to be applied to the support of public schools, and the levy of local taxes for the same purpose. By a second act of the same year the legislature created an Interior Department charged among other duties with the educational interests of the republic. A supplementary law provided for the appointment of a commissioner of education in each county, subject to the Secretary of the Interior. Prior to 1869 missionary societies had been actively engaged in efforts for the instruction and elevation of the people of Liberia, and the two principal church associations represented in the field, the Methodist Episcopal Church of the United States and the American Protestant Episcopal Church, had already made great progress in establishing schools when the government system was inaugurated.

In 1900, or thirty-one years after the passage of the first education act, the government was excited to new effort in this matter, and the legislature provided for the appointment of a superintendent of public instruction charged with the immediate direction of public schools throughout the country. Specific regulations were at once issued for the guidance of teachers and local school officers. The provision for a local school tax had proved futile, and the legislature assumed the support of the public schools by an annual appropriation.

As to the actual provision of schools in this republic, the latest reports give the following particulars. The Methodist Episcopal Church maintains schools in every county, having a little more than a thousand pupils on their rolls, including aborigines and Americo-Liberians. The former comprise about 57 per cent of the total number, and their ratio is steadily increasing. The central school of this system is the College of West Africa, located at Monrovia. It was founded in 1839, and accommodates about a hundred students in the several departments, theological, collegiate, and preparatory. Special provision is made for industrial training. Many of the leading men and women of the country, including a large number of efficient teachers, were educated in this institution. The Protestant Episcopal Church maintains many schools, which center about four principal institutions, namely, Epiphany Hall, at Cuttington, Cape Palmas, comprising a high

school, collegiate department, and divinity school, a girls' school and orphan asylum at Mount Vaughan, near Cape Palmas, St John's School, for boys, at Cape Mount, and a school for girls at Clay-Ashland. The latest statistics show a total of fifty schools in this system, of which twenty-seven were for day pupils only and twenty-three boarding schools. The enrollment in the schools in 1905 was about 1500, of which number 74 per cent were native Liberians. The schools of this system are under the close supervision of a resident bishop. The average annual salary of the teachers ranges from \$150 to \$300, which exceeds the average in other mission schools. The Lutheran Church also maintains a few schools among the native Africans at the Muhlenberg station.

The government school system in each county is under the direction of a local school commissioner. The latest statistics give a total of 102 schools, each under a single teacher, and a total enrollment of 3320 pupils, of whom about one fourth are aborigines.

The chief national institution is Liberia College at Monrovia. The institution was founded by the efforts of the Massachusetts Colonization Society, and was placed under the control of two boards of trustees, one representing the society and the other the legislature of Liberia. The college building was furnished by the Boston board at a cost of \$20,000. Liberia gave the twenty acres which form the campus of the college and a grant of 1000 acres of land in each of the four counties of Liberia as an endowment. The college was opened for students in 1862, and after varying fortunes passed to the sole control of the republic in 1890. Since 1900 the income of the college from public sources (taxes and endowment) has averaged about \$25,000, annually, and additional funds are also supplied from America. The college has the benefit of several public scholarships endowed in the names of men who have rendered unusual service to the country. The latest statistics show a registration of 120 students, including both young men and young women, and a corps of twelve instructors. The college is the alma mater of the most prominent citizens of the country, among the number being the former chief executive, Honorable Arthur Barclay.

Industrial education is a feature of both denominational systems. At the White Plains' school and the Sinoe River Industrial School, sustained by the Methodist Episcopal Church, students are taught building, woodwork, masonry, brickmaking, farming, and the cultivation of cotton, ginger, and rubber. The College of West Africa has a printing department, in which job work is done, and the *Liberia and West Africa* and other papers are printed. Most of the work is done by native Africans. In the college proper the girls are trained also in domestic economy, housekeeping, dress-

making, fancy work, and kindred arts. In the Protestant Episcopal schools industrial training is given at the four chief centers of education. At Epiphany Hall students are taught the cultivation of coffee, cotton, and rubber, at St John's School, Cape Mount, there is an agricultural department, in which rice is raised with success, and efforts are being made to secure facilities for teaching other industrial arts. A beginning has been made in industrial training in the public schools. At Rick's Institute, at Kai-Poo, the work consists chiefly of the cultivation of coffee, and the farm yielded 3000 pounds in 1902, 1600 in 1903, and 1400 in 1904. An excellent printing department has been fitted up at Liberia College, and other industrial work is being gradually introduced.

The American Colonization Society has aided schools in Liberia from time to time, in particular the school at Mt Coffee, forty miles from Monrovia. This school has been the especial charge of the Mt Coffee Association of America, of which Dr Edward Everett Hale was an interested and active member. The Colonization Society, as trustee for a fund left for schools by a Mr Graham, supports two schools, which bear his name. Graham School, No 1, is located at Greenville, Sinoe County; reports from teachers beginning with the year 1905, and ending with Mar 31, 1911, show the total attendance of scholars to have been 1261, Liberian boys and girls, 993, native boys and girls, 268. Graham School, No 3, is located at Royesville, Montserrado County, the report of the teacher for the five years ending Mar 31, 1911, shows the total attendance of scholars to be 447, Liberian boys and girls, 243, and native boys and girls, 204. The present President, Daniel Edward Howard (inaugurated Jan 1, 1912), is emphasizing the needs of improving the public school system, of agricultural education, and of Liberia College. I M C

#### LIBERTY COLLEGE, GLASGOW, KY —

An institution for the higher education of women, founded in 1874. In 1911 there was amalgamated with it the Florence University for Women, Florence, Ala. Preparatory, collegiate, normal, commercial, music, art, and domestic science departments are maintained. The entrance requirements are equivalent to about three years of high school work. The degrees of B A, B S, B C, and M A are conferred.

**LIBRARIES — Historical —** *Babylon and Assyria* — The temples of the ancient cities

which lie between the Tigris and Euphrates, such as Telloh, Nippur, Sippar, Borsippa, and Nineveh, were administrative and literary centers as well as the shrines of gods. From ten to thirty thousand inscribed clay tablets in each temple preserved official record of battles and of the divinations which foretold success or failure. There were also treaties, petitions, diplomatic letters, laws, deeds, and church rituals. These constituted royal or national libraries, presided over by Nebo the god of learning, and under the care of the king-priest or a high official.

Later when Hammurabi (c. B.C. 2200) became chief ruler in Babylonia, Mardik was advanced to be the head of all gods, and Babylon became the center of records and learning. Hammurabi's famous laws were cut into the wall of the temple. These records and others were brought together by Ashurbanipal (B.C. 671-626) at Nineveh when he became King of Assyria. Copies of inscriptions on monuments of victories and of all national legends were here recorded on clay tablets and cylinders. These were arranged by classes, were catalogued, and indexed by title. Many of those which describe divinations had excellent drawings to illustrate the text. A century later (Ezra v, 17) Darius ordered a search to be made in the hall of books at Babylon for a decree regarding the house of God at Jerusalem.

The temples were great schools, and popular, because preferment, as in the Middle Ages, came through the priestly office. The libraries had many easy texts and vocabularies for boys to study. Ashurbanipal says that he had studied at the temple, probably as a youth.

*Egypt* -- At El-Amarna, the Egyptian capital of the Pharaoh Akhuateon, who tried to uplift religion and free art from convention, much of the national library has been found, composed chiefly of correspondence with provinces and with kings in Western Asia. These archives were in charge of Tetou-nou, an Egyptian, whose assistant was Shamas-Niki, a Babylonian. The hieroglyphic writings of Egypt never supplanted the cuneiform of Babylonia as the language of culture and diplomacy, and Shamas-Niki must have been indispensable. The papyrus plant which furnished food, fuel, and clothing for Egypt became the fragile medium for perpetuating her writings, until parchment or prepared skins came into use. There were many papyrus collections in Egypt (see Richardson's *Some Old Egyptian Libraries*, 1911); but the great library at Alexandria grew up under foreign influences, the product of one of many long periods of foreign domination of the Nile valley.

*Greece* -- Greece left records of books, book selling, and schools, but little of libraries. Demetrius Phalerus, poet and orator, honored with as many statues as there are days in the year, fled to Alexandria, and there advised Ptolemy in his plans for a great library, al-

though Aristotle is said to have aided in the arrangement. Aristotle's own library (*Stabo* XIII, 1, § 54) passed to Theophrastus and from him to Neleus of Scepsis, where it lay hidden to escape the rapacious bibliophile kings of Pergamum until bought by Apellicon of Athens. Sulla the dictator and book-lover carried the collection to Rome to have its texts copied and spread abroad.

From Ephesus, where, we are told, there was a book chained to the door of Diana's temple, came Zenodotus (B.C. 280) to manage the Alexandrian library, to walk in its colonnades with peripatetic teachers, and to dine in rooms set apart for its students. This was the mother library, distinguished thus from the daughter library in the temple of Serapis. The older collection was in part destroyed by Cæsar, but Antony gave 200,000 manuscripts of Pergamum to Cleopatra for the Serapeum. Of this great library fleeting and uncertain glimpses appear in 391, when Theodosius ordered its destruction, a generation later when Orosius says that he saw ancient books in Alexandria, and in 640, when Amrou, the great caliph Omar's lieutenant, is said to have used the remnant for fuel.

*Rome* -- M. Terentius Vairo, author of a work entitled *De Bibliothecis*, now lost, was commissioned by Julius Cæsar to collect books for a library. Under succeeding Cæsars Rome became a city of libraries, to which students of the many schools of oratory and philosophy resorted. Telephus, a grammarian of Pergamum in A.D. 117, is said by Suidas to have issued a *Notitia librorum* which described minutely the libraries of his time. Forty years earlier Crates, ambassador from Pergamum, probably stimulated an interest in libraries while lecturing on grammar at Rome. C. Asinius Pollio, the general, poet, and friend of Vergil and Horace, founded the first library in Rome from spoils of his Illyrian campaign, B.C. 39. Pliny calls him "the first to make men's talents public property," but Plutarch claims this honor for Lucullus.

The Porticus Octaviæ, a typical Roman library between the Capitoline Hill and the Tiber, was founded by Augustus. It has temples to Juno and Jupiter, connected in the rear by a long schola, or hall for conversation. A space of equal length behind the schola had three divisions: a middle section, the curia, devoted to meetings, with the Latin library at the left and the Greek library at the right. About this compact building there was a double colonnade 443 feet by 377 feet, to provide, as at Alexandria, a meeting place for master and pupils. Rome had nearly thirty libraries, to which Vespasian and Trajan made large additions. Their manuscript rolls were kept in bookcases or presses, inlaid, and surmounted by busts, unless there were portraits on the walls. There was usually a director with a subordinate in charge of each language. Men like Lucullus

lavished money on their libraries until Seneca spoke bitterly of books as "ornaments of dining rooms," reaching to the ceilings. He adds "Nowadays a library takes rank with a bath-room as a necessary ornament to a house. I could forgive such ideas if they were due to extravagant desire for learning" (*De tranquillitate animi*).

*Middle Ages.*—Christianity did not alter the form nor greatly abate the luxury in libraries. Eusebius, in his *History*, speaks of Bishop Alexander's library at Jerusalem (A.D. 250) as a storehouse of knowledge. St. Jerome worked in the library of Pamphilus in Caesarea in Palestine, and calls the founder a rival in zeal of Demetrius Phalerius and Pisistratus the tyrant. In the early Christian Church the apses on either side of the altar were used to store the altar vessels and ritual books. Thus one apse came to be used as a religious or monastic library. Christian enthusiasts retreating into the deserts and mountains to escape luxury needed books to keep themselves from ignorance. From them first came primitive library rules. Those of St. Pachomius (A.D. 292–345) were developed near Denderah in Upper Egypt. St. Benedict perfected library administration, and his successors influenced the government of early college libraries. (Clark, *Care of Books*) Monte Cassino, Saint Gall, and Cluny are examples of these Benedictine libraries.

In the manuscript era the monks of monastic libraries were also publishers and booksellers. The Abbot Loup of Ferrières kept a depot for books at S. Josse-sur-Mer. Others were at Wearmouth and Yarrow. Becker estimates that from A.D. 750 to 1200 there were 136 libraries in monasteries, with about 12,000 books in all. Of these about thirty were complete Bibles.

The two great figures in medieval learning were Cassiodorus (*qv*) and Alcuin (*qv*). Cassiodorus maintained a scriptorium where his monks copied the classic authors. Alcuin simplified the forms of written letters and stimulated scholarship. There are many woodcuts of the early years of printing which depict the monk in his library or scriptorium. Cassiodorus said "As the antiquarian copies the words of Christ, so many wounds does he inflict upon Satan." Here was the inspiration of medieval book making. Some of the best work was done by the Benedictine nuns, and trial pages written by nuns of St. Mildred's Abbey, Isle of Thanet, still exist.

By a law of recompense, the era of fanaticism that effaced or destroyed many manuscripts was followed by the age of printing. Books became cheap, and libraries leaped from a hundred to a thousand volumes. The scriptorium lost its influence, however, as a part of the monastic library. The *Ars Moriendi*, the *Biblia Pauperum*, the rude picture book of the Bible story, and the *Donatus* or popular grammar were multiplied beyond the dream of

Cassiodorus. Then movable type came, and the modern library was inevitable. Before the voyages of Columbus there were printing presses in 236 cities in Europe, with over a thousand printers. A million books were issued with good ink on durable paper before the end of the fifteenth century. The Bible, following Christian missionaries into every country, taught the world to read. "Some," said Fox, "gave a load of hay for a few chapters of St. James or of St. John in English."

Richard de Bury (*qv*), who finished his *Philobiblon* in 1345, shows forth the spirit which governed cathedral and university libraries in England. The general attainment of learning had grown to such proportion that Bishop Carpenter's librarian at Worcester in 1464 was required to be a graduate in theology and a good preacher. It was his duty to explain hard passages in the Bible, make lists of the books in his keeping, and examine the shelves each year on the Friday after the Feast of Relics (in January). At St. Martin's, Dover, now part of Dover College, the administrative details, worked out very thoroughly, have been preserved. At Pembroke College the titles of books were written on parchment attached to the left half of a board. The right half was covered with a thin layer of wax, on which the name of a borrower might be scratched in line with the book's title. The borrower deposited a "pledge," sometimes the value of the book, or an agreement in writing.

Education in 1400 is reflected in the character of college libraries in England. Theology and kindred subjects claimed three fourths of all the college books, with one fourth devoted to grammar, poetry, music, medicine, arithmetic, geometry, and astronomy. The proportion was not materially altered in colonial New England, but in the Southern colonies private libraries reflected a later and broader taste.

*Great Libraries Founded in Early Modern Period.*—The Vatican library at Rome has historic origins in church records dating from the second century, and was associated in the fourth and fifth centuries with Popes Damasus and Hilary. With Boniface VIII, a true pontifical library began, when he ordered a catalogue to be made in 1295. These books were scattered in the fourteenth century, some going to Assisi, where they may still be seen. Nicholas V (1447–1455) was a book lover, collecting for the common convenience of all learned men, and fifteen years later Sixtus IV provided a building for the new collection, appointed Platina as librarian, and made the modern Vatican library a reality. From 1475 to the time of his death in 1481, Bartolommeo Platina fitted his library with banchi and wall cases, added paintings by Ghirlandajo and Melozzo da Forlì, and catalogued the books. There were the Latin and Greek rooms, the *Bibliotheca Secreta* and the *Bibliotheca Pontificia*. Platina and his three pages slept in an adjoining room.

Juniper was used to fumigate, fox tails to dust, and brooms to sweep the library. A notice of the time of Julius II asked readers not to quarrel nor to jump over the desks. A pleasant description of the library will be found in Montaigne's *Travels in Italy* in 1581. Scholars were first admitted in 1888. Much might be said of the Laurentian library at Florence and of the origin of old collections in other parts of Europe. The familiar print by Woudanus in 1610 of the library of Leyden University represents gentlemen with their hats and cloaks on, followed by dogs, going from case to case to consult the chained books.

Edwards, in his *Memoirs of Libraries*, has given the story of the plundering of monastic libraries in the sixteenth century, when manuscripts were used to light candlesticks, to rub boots, and to wrap grocers' bundles, "and some they sent over sea to the bookbinders, not in small number, but at times whole ships full, to the wondering of the foreign nations." Books are still found with pieces of written parchment used in the bindings. In some college libraries the desks were sold since no books remained.

A century later a great need stimulated renewed interest in book collecting. Humphrey Chetham in 1651 saw the value of "godly English books, proper for the edification of the common people," and founded chapel libraries and a town library in Manchester. The Reverend Thomas Bray, whose life was one of amazing energy and results, promoted deanery and parish libraries all over England and parish libraries in the English colonies to preserve the clergy from ignorance.

The British Museum had its origin not as a hall of official records, but in three great collections illustrating English history. The death of Sir Hans Sloane in 1753 brought about the act (26 Geo. II, 1753) for the purchase of his treasures of art and books, together with the Harleian manuscripts, the two collections to be united with the Cottonian manuscripts, already the property of the nation, under a board of trustees. The British Museum was opened as Montague House in 1759, the Royal Library of the Kings having meanwhile been given by George II. The romantic career of the late Sir Anthony Panizzi, Italian refugee, librarian and scholar, resulted in placing the British Museum in the front rank. "He governed his library as his friend Cavour governed his country," wrote Dr. Garnett, "perfecting its internal organization with one hand while he extended its frontiers with the other." The printed catalogue, from troubled beginnings in 1834, is now complete, and represents a great bibliographical achievement, closing with the year 1900. Of earlier origin, the Bodleian library at Oxford, opened in 1602, was the first "public" library in Europe; the second was that of Angelo Rocca, opened at Rome in 1604. The John Rylands Library at Manchester, begun in 1890, took high rank two years later

when the ancient Althorp Library of the Earls Spencer was purchased. This collection, associated with the genius of Dibdin, illustrated by examples the whole range of the history of printing.

The Bibliothèque Nationale in Paris can be traced to a collection of records in the Louvre in the time of Charles V. Guillaume Budé was the first *Maître de la Librairie du Roi* in 1544, and in 1556 a copy of each book printed in the country "with privilege" was by law deposited in the library. For several centuries two library families, the De Thou and the Bignons, held a sway of varying power, building up the collection by unceasing labor and foresight. In 1721 the books were removed to the Palais Mazarin, the Bignons serving as librarians from father to son from 1642 to 1784. The revolution sent its spoils of churches and country houses, swelling the accumulations of centuries to a total of nearly three million volumes. A catalogue is now (1912) being printed.

All the important countries of Europe have royal or national libraries, varying in size and administrative efficiency. The Imperial Library at St. Petersburg, with over a million volumes, is one of the most valuable in the world, and is freely open to scholars. In most cases, however, the great libraries of the continent are the accumulation of time rather than of systematic effort, and from them down to the humblest civic collection there is rarely any liberal control comparable to that which is everywhere characteristic of American libraries.

*America* — For two centuries at least after the arrival of Winthrop in Massachusetts Bay, Boston was the literary center of the English colonies. Her clergy and her civic rulers could not be content without writing as well as reading books. A library established in the Town House at Boston through the will of Captain Robert Keayne, dated in 1653, was composed of books in English, and the idea may have been suggested by the small municipal collections formed at the English Norwich and elsewhere as early as 1608. New York owes its advent into library history to Reverend John Sharpe, chaplain at the fort, who proposed in 1712-1713 a public school, a public library, and a catechizing chapel. The library was to be free to all Sharpe's books, and those of the corporation library of 1728, sent over by the Society for the Propagation of the Gospel, together with the much finer collections of the New York Society Library, founded in 1754, were all swept away during the Revolution.

Franklin once said that in his boyhood there was not one good bookstore south of Boston. When a lad, he went to Philadelphia and projected there in 1731 the first subscription library in the colonies. Franklin says: "I set on foot my first project of a public nature, that for a subscription library. . . I was not able, with great industry, to find more than fifty persons, mostly young tradesmen, will-

ing to pay down for this purpose forty shillings each, and ten shillings per annum. On this little fund we began." This collection eventually became the Philadelphia Library Society, and half a century later was strengthened by adding the Loganian library, which had been founded in 1745 through the generosity of James Logan, famous as the secretary of William Penn. The Redwood Library, established in Newport, R. I., in 1747, belongs to this period. A similar library, also an institution for self-improvement, was begun in the following year by some seventeen young men of Charleston, S. C.

As early as 1774 the *Connecticut Courant* made the assertion that the need of public libraries was "too manifest to be denied", but up to 1850 the public library had no such character as it has to-day. It is true that Boston and New York made spasmodic attempts at city libraries, but in reality the only libraries during this time were the Bray or parish libraries, mostly unused, and the subscription libraries, which flourished because they were near by and were not necessarily self-sustaining.

The first ten years of the nineteenth century, influenced by the conditions in France, show a great intellectual awakening. Clubs of all kinds, and especially learned clubs, sprang up, and almost all had a reading room or a library. From this beginning many atheneums or scholars' libraries came into being, from New England to Georgia.

During this same period the establishment of state and national libraries was begun. New Hampshire, the pioneer, had a colonial library as early as 1770, which was reestablished as a state library in 1818. New Jersey followed with a library as early as 1796, though it was so much broader in scope that it has served as a type to guide many later state libraries. It was a sufficiently elastic model to allow for the changes which time and varying conditions have imposed, enlarging the original conception into a far wider idea of its duty to the people, than that of a merely legislative function. South Carolina, Pennsylvania, and New York, the best known of the early state libraries, were all founded before 1818. In 1800 the national government established a library. Its beginnings were so small that its first catalogue (1802) was hardly necessary. When the British took Washington in 1814, the library was burned, and twice since, in 1825 and 1851, fires have occurred. Jefferson's library was purchased in 1815, and was the first of many famous collections to be added. The Library of Congress now aids her libraries through printed catalogue cards, bibliographies, and other material.

All these were tendencies away from libraries which were under private control, and the tendency became more marked when towns like Salisbury in Connecticut (1803) and Peterborough in New Hampshire (1833) established libraries with town funds. These

foreshadowed the true public library, but it was not until George Ticknor of Boston grasped the significance of the great benefit that would come when books were free to all, that the movement came to its fruition. The first convention of librarians was held in New York, Sept. 15-17, 1853. The fact that fifty-three delegates were present shows how great was the awakening, both among scholars and among librarians.

In 1848 William F. Poole printed a modest index to the many periodicals which had become useless and because of the impossibility of finding the material hidden there. This was the origin of Poole's *Index*. At about the same time other men came into prominence in the library world, which at this time centered around Boston. Jewett failed to create a National Library, came to the Boston Public Library (1855), and made himself widely known by his rules for cataloguing. Thirteen years later Justin Minor succeeded them. At this time Poole was about to go to Cincinnati, and Cutter prepared to succeed him as librarian of the Boston Athenæum. These men and many others met in Philadelphia in 1876 and founded the American Library Association, with the *Library Journal* as its organ.

**Recent Development** — *Scientific Library Management* — Edwards (*qv*), Pamizzi, and Ewart (*qv*) in England, and the leaders in America laid the library world under a debt hard of comprehension in the present day of universal progress. Library devices of all kinds were being perfected and improved at this time on both sides of the Atlantic. New rules for cataloguing were being tried, and Dewey and Cutter were bringing to perfection their system of classification. See **LIBRARY CLASSIFICATION**.

Women at this time had little connection with libraries, but this has grown greater as their sphere of activity has grown wider. Mrs. Anne Waddell, a woman of affairs in New York, was named in the charter of the New York Society Library in 1772. During the first half of the nineteenth century women's sole literary interests were such as might be derived from the circulating libraries in the stationers' or bakers' stores. A few very crude scholars were allowed to use the libraries of general literature, but the general attitude of mind toward such use was reflected by Charles Folsom, who protested in 1855 against women having access to "the corrupter portions of the polite literature."

In 1850 Harvard had 68,000 volumes, the largest collection in America, the Library of Congress about 46,000, the New York Library Society 30,000, and the Library Company of Philadelphia 55,000, the second in size. To-day these would not seem large collections for any prosperous town.

The library movement in the United States is indebted to many forces for its success. The

Mathers, Prince, Sharpe, and others of the colonial clergy fostered the collection and care of books. Franklin, a great social and scientific factor in our development, emphasized the library as an aid to the skilled laborer. Following the American Revolution and its period of inaction, French ideals had an awakening impulse, caught up and carried on by the far-reaching lyceum system of rural lectures. No doubt also the articles by Edward Edwards and the speeches of Ewart had their echo on this side of the Atlantic. Certainly the *Report of the Commissioners*, appointed by the House of Commons to inquire into the constitution and government of the British Museum under Panizzi, and published in 1850, must have interested and aroused men interested in books, in administration, and in social forces.

*Library Legislation* -- An enlightened opinion has in some states forced special library legislation, but more often a few devoted men have obtained the laws that in time create a regard for libraries. The library law of New York, passed in 1835, under which a school district could raise a sum of money for the purchase of books, established the principle of taxation for the support of libraries. New Hampshire passed a very simple library law in 1849, with no limit as to appropriation and no conditions as to management. Massachusetts enacted in 1851 a brief law under which libraries multiplied rapidly in the commonwealth. Maine in 1854 passed an unsatisfactory law, permitting the levy of a dollar on each ratable poll to establish libraries, and twenty-five cents per poll for maintenance. Vermont did little better in 1865. The Ohio law of 1847 tied the library to the educational system. In 1872 Colorado passed a good law, and Illinois devised an elaborate and thoroughly satisfactory act which has influenced many states, New Jersey, Wisconsin, Michigan, California, Missouri, and others. Some sections of the country were for a long time very backward in library legislation, including Connecticut, Pennsylvania, and even New York, where the fairly convenient school district system was not altered till 1892.

The State Library Commission, which was established by Massachusetts in 1890 to foster town libraries, set an example that has been followed throughout the country; with increasing powers and a firmer conviction of the work to be accomplished, state commissions have grown in importance and in the scope of their work for library extension. In many states the cooperation of the state commission and the state library has made the use of books a vital and far-reaching force for intelligent citizenship.

Library history in the United States has been of short duration, but, with no traditions to forget and no customs to break, progress has been rapid. History, as far as it has been made, has had less of the dignity of mere age and more of the fruit of real achievement. One has only to study

library history in France, Germany, or Italy, to realize that what has been done in the United States toward establishing an intimate relationship between good books and the social life of all classes has been pioneer work.

*Free Public Libraries.* -- Library progress in the sociological sense must be studied in three sections. England, although handicapped by inability to free her library and museum property from taxation, began before 1850, under able leaders, her campaign for free libraries. America, recognizing early the right to levy taxes for the establishment and maintenance of public libraries, made greater progress along seemingly radical lines. The Continent, crippled by social and economic conditions, has only very recently welcomed modern ideals.

In 1700 John Evelyn said that Paris had more libraries than were in the three kingdoms of Great Britain, and Gibbon declared in 1800 that no scholarly work could be done in English libraries. A conference at Manchester half a century later agreed that since Gibbon's day little improvement had been made, and William Ewart was asked to begin a parliamentary fight for a library law. The bill of 1845 "for encouraging the establishment of museums in large towns" was passed, it allowed half a penny in the pound to be levied for land and buildings for museums in large towns, but no specimens or books could be bought. Edward Edwards, for many years on the staff of the British Museum, took up the study of library conditions at home, on the Continent, and in the United States, embodying his researches in articles published in 1847 and 1848. Ewart then brought in a bill, which met with vigorous opposition and the most absurd arguments before its passage in 1850. This act was permissive for towns of 10,000 inhabitants and over, kept to the same inadequate rate, and made no provision for the purchase of books, but it was distinctly for libraries as well as for museums, although the latter have always overshadowed public libraries in English legislation. Subsequent acts advanced the rate to a penny, allowed the purchase of books and newspapers, permitted money to be borrowed for the erection of buildings, and extended these privileges to Scotland and Ireland. So great was the confusion arising from conflicting library acts that in 1894 they were consolidated, making a nearly uniform law for the United Kingdom.

The rate limit has hindered library progress, and taxation of library property has still further decreased the net return from a rate already too small for healthy growth in populous communities. London, with no central government until 1899, has had a slow development. English libraries in early days depended too much on mechanical devices; the librarian was a custodian and clerk rather than an administrator, and his influence was limited. Until recently there have been no training schools for young men and women who fill the minor places,

so that these have been less intelligently managed than large libraries which could tempt officials from the British Museum. An American is apt to think that the English librarian does not trust his public enough, that he does not do enough for schools, for rural districts, and in the way of cooperation with neighboring libraries. The Englishman considers our classification on the shelves too close and too inflexible, and he experiments cautiously with the many social plans by which Americans bind the community to the public library.

In America Ticknor set the pace for library progress when, in 1851, he spoke of his aim for the proposed public library in Boston. "I would establish a library which differs from all free libraries yet attempted; I mean one in which any popular books, tending to moral and intellectual improvement, shall be furnished in such numbers of copies that many persons can be reading the same book at the same time, in short, that not only the best books of all sorts, but the pleasant literature of the day, shall be made accessible to the whole people when they most care for it, that is, when it is fresh and new."

But even in America the free public library has come with wise slowness into favor. As late as 1876, when one hundred and three delegates met at a conference of American librarians, only fourteen represented institutions of the modern free public library type. Libraries maintained by shareholders and by annual subscribers still predominated. With the rapid advance of the free library the scope of its work along social lines has become a subject for debate. We are not far from that condition referred to in 1850 by a member of Parliament who prophesied that the working classes would soon be asking for "quoits, peg-tops, and footballs." Sunday opening, first tried in Cincinnati in 1870, was an early step in the radical movement in America. Work with children, now recognized as essential in a good library, attempts to attract and hold the young when they first learn to read. Indeed, story telling and games are introduced in branches of great city libraries to win the very young and the foreign born. University extension lectures, given on certain evenings each week and on Sundays, bring older people to the building and give them predigested treasures from books and art. More liberal rules for the circulation of books (the two-book system and special cards for teachers), free access to the shelves or to special standard collections, and even free delivery from library to home, all illustrate the endeavor to make the free library indispensable.

A distinct effort is now made to educate taste in architecture by new ideals of excellence in buildings, but the façade follows the plan and is not merely a pleasing exterior. Books on library planning fortify the librarian against the inexperienced architect who desires effect only.

*Library Methods* — The American missionary spirit, radical though it may be, has had its

influence in the old world as well as in the conservative communities of the new. Certain mechanical improvements, such as the decimal and expansive systems of classification for placing books on the shelves, indexing the books of the library on cards instead of in ledgers, making a charging record for books taken out of the building so that statistical information may easily be compiled, and uniform cataloguing rules, adopted in preparing cards to be issued by the Library of Congress, are revolutionizing the routine of library administration. The librarian, while he may still be a "missionary of culture," must recognize that his vocation calls for business ability.

English and American methods, though differing, are not fundamentally divergent after all. The Continent, however, can show little enlightened library development outside a few isolated examples in Holland, Switzerland, Germany, and Sweden. In Germany the dual library system, a *Stadtbibliothek*, or sleepy municipal library in the main street, and a *Volksbibliothek* or cheap fiction library on the side street, has delayed the coming of the all-round large public library. Social club libraries also have satisfied the more intelligent members of the community, who are bound together by a love for art, music, archaeology, or science.

France has few cities where the public seem to want libraries, and zeal is not expected from poorly paid librarians. The scholarly librarian, however, still survives in some historic French towns. What France lacks in organization Italy carries almost to an extreme. A library assistant in Italy can be transferred from city to suburb or to a distant city, finding the same system everywhere. In the northern countries of Europe people's libraries are still parish charities, except where Miss Valfrid Palmgren, through addresses and writings, has introduced American methods and aims. The censorship in Russia has crushed library progress there, and throughout many square miles no books are accessible to the public. The works of a contemporary poet under the ban of the censor could not be found in a library which honored him by bearing his name. Still, in Russia, and in Siberia, interesting little libraries may be found where a librarian has been born for the task, undismayed by conditions which prevail all about him.

Germany and Switzerland have attempted catalogues on a great scale, but in most European capitals the catalogues are inaccessible, or inadequate, and the service is very slow. Munich, Stockholm, and Brussels have been famed in the past for helpful employees and convenient appliances, but administrators die and policies change. The real library movement is to be seen at Charlottenburg and Essen in Germany, at Dordrecht and Groningen in Holland, at Stockholm, and at several other places where modern methods are but just coming into vogue. Foreign scholars have

attended English and American library conferences, and have admired what they saw, but they have been slow to believe that these radical methods could be made successful in Continental cities. They are, however, very gradually making the experiment. C. K. B.

**School Libraries** — *District School Libraries* — The district school library movement antedated the modern public library movement in this country by about forty years. Its original impulse came from educators who saw that if the State was to gain intelligent citizens, as a result of its investment in education, the young must not only be taught reading, but must be given good books to read.

New York was the pioneer, and a law was passed in 1835 permitting the voters of any school district to levy a tax of \$20 to start a library, and \$10 annually to maintain it. Thus permission failing to appeal to the rural taxpayer, the legislature of 1838 passed a law appropriating \$55,000 annually for the establishment of libraries in every school district of the state, with the provision that after three years the money might be spent for books or for teachers' wages, at the discretion of the district. These were not to be strictly school libraries for the use of the pupils alone, but were also intended for the use of the people of the district.

The example of New York was followed by Massachusetts, which, through the efforts of Horace Mann (*q v*), passed in 1835 a permissive school district law, and in 1842 added the stimulus of a state appropriation of \$15 to each district that should raise an equal amount.

Following the lead of New York and Massachusetts, seventeen states passed more or less effective laws providing for district school libraries, as follows: Connecticut, 1839, Rhode Island and Iowa, 1840, Indiana, 1841, Maine, 1844, Ohio, 1847, Wisconsin, 1848, Missouri, 1853, California and Oregon, 1854, Illinois, 1855, Kansas and Virginia, 1870, New Jersey, 1871, Kentucky and Minnesota, 1873, and Colorado, 1876.

The results of this legislation were in the main disappointing. Jewett's *Notices of public libraries in the United States*, published by the Smithsonian Institution in 1851, reports 9505 public school libraries in all, containing 1,522,332 volumes, of which 1,338,848 volumes were in New York, 91,539 in Massachusetts, 47,220 in Michigan, and 19,637 in Rhode Island, no other state reporting more than 10,000. In the Bureau of Education's special report on libraries in 1876 the total number of volumes in school libraries had declined to 1,365,407. In New York State, where alone the school libraries were very generally established, the number of volumes in libraries fell from over 1,300,000 in 1851 to 825,000 in 1892, and most of the annual appropriation had come to be devoted to general school purposes.

*Success of the Movement* — Two reasons are usually assigned for the comparative failure of

the school library movement in the country. First, defects in legislation; many of the states failed to give state aid or gave it only intermittently or failed to provide for the supplementing of state aid by local taxation, thereby keeping up local interest in the libraries. Second, defects of administration, there was seldom any supervision over the selection of books, and the local school authorities were not accountable to any central authority for the management of the libraries. But underlying both of these reasons was the fact that this early school library movement was strictly a school enterprise. The educators originating it did not realize that books alone do not make a library, and that only where organized into libraries do masses of books become available for use. To be efficient a library should be well chosen, classified by subject, the contents of the books brought out by analytical cataloguing. The books need to be mended and rebound, they should be charged when in circulation, both for safety and in order that their use may be recorded. All this is a librarian's business, not a teacher's, and in the forties and fifties librarians themselves had not yet worked out methods of efficient library administration, — library science was in its infancy.

American librarianship did not become an organized profession until 1876. By that time the great increase in the number and size of libraries in the country (from 694 libraries with 2,201,632 volumes in 1851 to 3647 libraries with 12,276,964 volumes in 1876, exclusive of school libraries) had forced librarians to create more uniform, economic, and efficient methods of administration, and for the first ten or fifteen years the sessions of the American Library Association were largely devoted to questions of library technique, — cataloguing, classification, charging systems, shelving, etc. Very dry and uninspiring subjects, but thanks to the fine quality of thinking expended on them and to the *esprit de corps* that put every improvement at the disposal of the whole profession, these problems were solved so successfully that the enormous expansion in the number and size of libraries during the last twenty-five years was accomplished easily and has been accompanied by an even greater expansion of use. According to the Bureau of Education *Reports* there were in 1884, 2988 libraries of over 1000 volumes in the United States, containing in all 12,376,473 volumes, with a total circulation of 10,899,469, in 1908 there were 5640 libraries, with 62,628,541 volumes and a circulation of 82,222,584. In other words, while the libraries have doubled in number, their size has multiplied by five, and their use has increased nearly eightfold.

With problems of library administration in a fair way to be settled, librarians next turned their attention to improving the quality of books in the libraries. Principles of book selection were evolved, and bibliographic tools for the evaluation and selection of books were forged, a partial

list of which will be found appended. With these methods and tools librarians were now equipped to aid educators in their endeavor to make the school libraries a dynamic element in education.

In 1888 Melvil Dewey, who had perhaps done more than any other man to promote administrative efficiency in American libraries, was made State Librarian of New York, and thus the organizing genius of the new librarianship was brought to bear on the unsatisfactory conditions of district school libraries. Mr Dewey found that the \$55,000 still appropriated under the law of 1838 had been almost wholly diverted to general school purposes, that in many cases the libraries had been dispersed, and that where they survived, the original purpose of supplying books to the people of the school district had been lost sight of, and that the books were regarded as part of the school equipment. A new law drawn up by Mr Dewey transferred those that had developed into public libraries to the regents of the university, to be carried on in connection with the state library, while the appropriation of \$55,000 (subsequently increased to \$100,000) was continued, but it was specifically directed that it be administered by the Department of Public Instruction for pedagogic and reference books for the use of the teachers and pupils. That rule, however, was annulled in 1910, and school libraries in communities that have no public libraries may be opened to the public. Since 1892 the number of volumes in the school libraries has increased from about 800,000 to 3,135,408 volumes, selected from lists approved by the state authorities and bearing on the state course of study. The state education department reports that the libraries are well cared for; that in some cases the librarian of the local public library supervises the school library, and that in many cases there are trained librarians in charge of the school libraries.

State commissions to stimulate the establishment and to advance the efficiency of libraries have been established in thirty-three states, beginning with Massachusetts in 1891, and in many states the school libraries have come under their influence. In Illinois the library commission lends books to county school libraries; in Minnesota the relation between the commission and the schools is very close,—the commission organizes school libraries and revises the list from which purchases must be made, the state superintendent of education employing a member of the commission's staff to care for school books. In Missouri and Nebraska the state library commissions are also in touch with the district school libraries. In Connecticut the State Library Committee (Commission) is directed by law to assist in the selection, purchase, and administration of school libraries and to lend them books and pictures. In Oregon the library commission is directly responsible for the district school li-

braries. A mandatory tax of not less than ten cents per capita for each child of school age shall be levied by each county having less than 100,000 inhabitants and set aside for school libraries. This is apportioned by the county superintendent, who must report to the Oregon Library Commission the amount apportioned to each district and the number of school children in each district. During July of each year the local school authorities must select from lists prepared and furnished by the library commission such books as are desirable for their district, the aggregate mailing price of which shall not exceed the apportionment. This list must be sent to the library commission by Aug. 10, and the commission buys the books, thus receiving much larger discounts than each library purchasing separately could obtain. If the lists from any districts fail to be received by Aug. 10, the commission shall select the books for these districts. The county superintendent shall appoint a librarian who shall receive and have the care and custody of the books, and shall loan them to the teachers, pupils, and other residents of the district in accordance with regulations prescribed by the commission. When school is in session the library shall be placed in the schoolhouse, and the teachers shall be responsible for its proper care and protection.

A revival of effort to increase the number and improve the efficiency of public school libraries, due in part at least to direct or indirect stimulus from library sources, is felt all over the country and has been reflected in recent legislation. Only eight states (Arkansas, Georgia, Mississippi, New Hampshire, Tennessee, Texas, Vermont, West Virginia) have no school library system established by law.

An analysis of existing laws shows that they fall into three classes,—permissive laws, in which the district is allowed to tax itself for a school library, persuasive laws, in which the state grants aid to the district, usually duplicating the amount raised by the district, and mandatory, in which the establishment of school libraries is required, part of the school funds being set aside for the purpose, and some state official or body, superintendent of schools, or library commission being made responsible for the enforcement of the law.

Only the exceptionally energetic school authorities or progressive communities avail themselves of the privileges granted by a permissive law. When the inducement of state aid is added, the moderately energetic and intelligent will take advantage of it, but a mandatory law, the execution of which is intrusted to state authority, will overcome the inertia of the great mass, and will achieve the desired result of a well selected library in every public school in the country.

The essential points to be covered by a good school law are:—(1) A mandatory minimum annual tax levy by county. (2) Compulsory selection from a well chosen list made by some

recognized and responsible authority (3) A central purchasing agency and a state contract price. (4) A definite and fixed time for annual purchase (5) Suitable rules and regulations to prevent scattering of the books

The Oregon law described on page 15 is especially to be commended as providing all these requirements. A brief résumé of the laws relating to state aid for public school libraries will be found in *Library Journal*, Vol XXXVII, 1912, pp 312-315

*School Libraries in Towns and Cities* — School library legislation has in the main concerned itself with the problem of the country school, while library work in city schools has largely developed along the lines of cooperation between the public library and the schools

To-day practically all of the public library systems in the cities of the United States have organized school departments through which classroom libraries are placed in the schools. In Buffalo the public library has placed 828 libraries in the grammar schools of the city, from which 418,753 volumes were circulated in 1910. In St. Louis traveling libraries are sent to the grade schools. In 1911, 176 traveling libraries containing in all 101,759 volumes, were sent to schools, and deposit stations are established in ten school buildings in which 59,238 volumes are placed. The Cleveland Public Library appointed a supervisor of classroom libraries in 1906, and the use of classroom libraries is being developed as rapidly as the resources of the library will permit. Detroit sends books for supplementary reading to the schools, circulating 77,869 volumes to school children in 1910. In Pittsburgh a catalogue of books for the use of pupils of the first eight grades was published in 1902 by a committee of teachers and librarians. A second, revised edition was published in 1907. Books are sent to 108 schools, about 100,000 volumes are circulated for home use yearly, and nearly twice that number used in the classrooms. The Newark Public Library has a school department, maintains a reference room containing books and periodicals for the use of teachers, and sends about 500 traveling libraries to classrooms.

The State Board of Education of New Jersey decided in 1911 that in all communities having free public libraries the board would recommend, subject to the approval of the local board of education, that the school library be administered by the public library, the circulating books, both fiction and nonfiction, becoming part of the working collection of the public library, with a distinguishing label, "Bought from the school library fund"; the pedagogical and strictly reference books are to be left in the school buildings where desired. The public library, on the other hand, must agree to furnish such books to the schools as may be needed in school work.

In New York City the work of supplying

classroom libraries is carried on by the board of education. This work began in 1893 before the consolidation of the several privately endowed and maintained libraries of the city into the present efficient public library system. In 1903 the board appointed the head of school work in the Buffalo Public Library as superintendent of school libraries of New York City. There are in 1911 more than 12,000 classroom libraries in the system, containing from thirty to forty books each, and with a circulation of about 8,000,000 volumes a year. There are also teachers' reference libraries in each school building.

The New York and Brooklyn Public Libraries supplement these school libraries by sending traveling libraries to the schools on request, and the New York Public Library has a school department which promotes reference work with the schools in the neighborhood of each branch of the library.

*High School Libraries* — In an article in *School Review* (Vol XIV, p 762) it is stated that "In every city school building there should be set apart as a library one large room furnished with comfortable chairs, in which should be found daily papers, suitable magazines, a liberal supply of the best fiction, travel, popular science, live, unabridged historical narrative, biographical essays. A modern card catalogue should be provided, which the students should be taught to use." A trained librarian to make the catalogue and to teach the use of it, as well as to stimulate the use of the books themselves, is needed to complete this picture. How many high schools of the country have established such libraries cannot be stated. The last Bureau of Education statistical report on libraries gives the number of school libraries in the country having over 1000 volumes as 1644, but private schools and the larger public school libraries are included.

In New York State there were in 1909 fifty-three high school libraries, established within the last twenty years, thirty of which are for the exclusive use of the schools, nine of them are for all grades, though housed in high school buildings, and fourteen of them combine the functions of high school and public libraries. Twenty-five of these libraries are in charge of librarians having previous library training or experience. A very important function of the high school librarian is that of giving instruction to the pupils in the use of the library, catalogue, indexes, and reference books. This is done systematically in several high schools in New York State, and the committee on high school libraries of the New York Library Association has been bringing the matter to the attention of high school principals. It has been done for some years in the Detroit Central High School; in other high schools, as at Newark, this instruction is given by the English teachers aided by the public library. In Cleveland the high school libraries are under the charge of the

public library. The schools furnish equipment and reference books, the library the librarian and a permanent circulating collection, and, in addition, lends books as needed, a regular delivery schedule being maintained between the high school libraries and the public library. Instruction in the use of books, based on a manual prepared by the supervisor of high school branches, is given regularly in all the high school libraries, for which credit is given in English.

*Library Training in Normal Schools* -- Most school libraries depend for their efficiency on the teacher, who must not only acquire enough knowledge of library economy to arrange, care for, and record the use of the books, but who should be able to guide the reading of the children and also to make the books contribute their utmost toward the enrichment of the school work. In order to attain this end, normal school students must be trained in the care and use of books and given some critical knowledge of children's books.

In a report of a subcommittee of the National Council of the N. E. A. on the relation of libraries to normal schools, in 1899, the question was asked if "the professional training of teachers had not reached that period in its development where the library must be one of the chief factors in the training of pupil teachers?" No mention was made in the report of any definite course in library training being given by a normal school, but an affirmative response was made to the query shortly after by the announcement of library courses by normal schools in different parts of the country. In 1902 a trained librarian was engaged by the Cleveland Normal School to give a course in "library use." In 1903 a study of juvenile literature was added to it. The course occupies three periods a week for three terms, is on the same basis of credit as other regular courses, and is required for graduation.

The Normal School at Whitewater, Wis., publishes a helpful outline of the work given there. The N. E. A. published in the *Proceedings* for 1906, and as a separate pamphlet (now out of print), a report on the subject which outlined a rather elaborate scheme of library instruction.

In several cities, Omaha, Neb., Newark, N. J., and Dayton, Ohio, among them, instruction of normal school students in library work has been carried on by the public library.

A number of state normal schools have given courses in library economy in connection with their summer schools, and in Michigan instruction in library work has been given at teachers' institutes.

*Branch Libraries in Schools* -- The movement to increase and to socialize the use of school buildings is of great interest to librarians and suggests the desirability of placing branches of public libraries in school buildings, more generally than has been done heretofore. This has already been started in Newark, N. J., and it has been carried on successfully for several

years past in Grand Rapids, Mich., where through cooperation between the Board of Education and the library regular branches of the library have been housed in the school buildings. These are conducted as public, not as school libraries, being open from 12 30 to 9 p. m., and containing books for readers of all ages. The superintendent of schools said recently that the greatest educational advance in recent years was the establishment of branch libraries in the public schools, as the presence of a library and a librarian added greatly to the efficiency of the general school work.

*Canada.* -- The district school library movement started in New York in 1835 and spread into Ontario, where an act was passed in 1850 providing for school libraries managed by local authorities under regulations prepared by the Council of Public Instruction. In accordance with the law, a classified catalogue was prepared by the Council from which alone selection could be made. The books were purchased by the Council, and, in addition, books to the value of the amount raised by the locality were given by the Council to each library. A record of each library was kept by the department and of the books furnished to it, thus preventing duplication. This law was much more enlightened than most of the corresponding legislation in the United States, and its results have been satisfactory.

*England* -- Sonnenschein's *Cyclopædia of Education*, 1906, states that in Great Britain any attempt at the formation of elementary and secondary school libraries has been due chiefly to purely voluntary effort, no assistance being given by the State. School libraries are not mentioned in the Educational Act of 1902. In an article in the *Library World* (1905-1906, p. 173) it is stated that about 9000 schools out of 12,000 are provided with libraries, the management of which varies in different localities. The larger number are entirely under the control of the individual education committees, while some are managed by a joint education and library committee. The public libraries of Great Britain have been too much hampered by restrictive legislation limiting the amount that could be raised by rates for library support to carry on work for schools like that done in the United States. A beginning, however, was made at Cardiff, Wales, in 1899. The school board raised the money, and the library committee undertook to administer the libraries, a joint committee of management being appointed from the two bodies. This has worked very successfully. The example has been followed by several other localities, and it indicates the line along which school libraries are likely to develop in the United Kingdom.

In London in 1908 a scheme was adopted by the County Council by which any public elementary school may be supplied with a small permanent library upon an application to the

libraries' committee by the headmaster or trustees, who must give surety to the Council for the safe custody of the books. A list of 200 books will be sent to the applicant with a recommendation that books be selected from it.

*France* — The idea of placing libraries in the schools dates back to the era of the Revolution, the *Décret sur l'organisation des écoles primaires*, 12 Déc 1792, directed that there should be formed in each school a small collection of books for the use of the pupils, and that it should be put in the care of an *Instituteur*. All the subsequent laws relative to elementary education recognized the importance of school libraries and dealt with means of introducing them into the schools. Successive ministries ordered the distribution of books to the schools, and between 1833 and 1848 more than a million volumes were distributed. But the indifference of the teachers and the laxity of supervision worked even more disastrously in France than in America, and in 1850 the school libraries had completely disappeared. (Buisson's *Dictionnaire de Pédagogie*, s v *Bibliothèques*, 1911 ed.)

In 1862 the ministry issued an order directing the establishment of school libraries in every public school for boys, and ordering the books to be placed in a bookcase in a schoolroom under the care of an instructor. No commune would receive books from the government unless it complied with this regulation. The State has since continued its gifts of books to school libraries, the volumes comprising both works necessary to the classroom work and instructive reading for the scholars and for adult members of their families. A special commission was created in 1865 to pass upon the books to be bought for school libraries, this commission, *Le Comité des bibliothèques de l'enseignement primaire*, issues catalogues of approved books from time to time.

The development of school libraries has been continuous since 1862. There are now in the neighborhood of 50,000 libraries, containing an average of 160 volumes in each, the regulations are definite, and the libraries are a branch of the public service.

*Germany* — There is no general school library law in Germany, and but little mention of school libraries in the educational legislation of the separate states. Württemberg and Saxony have recognized them, but the laws are vague and merely suggestive, and have not had much influence. So, while there are libraries in most of the higher schools and in many public schools, the school library has not the legal status in Germany that it has in France or Austria. The existing school libraries are in general for the use of teachers and pupils, and are not for popular use, as in France, though in country districts the public and school libraries are sometimes combined.

*Austria* — The Minister of Religion and Education issued an order in 1870 that a library should be established in every communal

school, regulations for the organization of the libraries were promulgated in 1871 and completed in 1875. The director of the school is to be responsible for the library, which is not only intended for the scholars, but for the people of the commune. The government has not given the school library movement the systematic support which it has received in France, and there are no general statistics of the number of school libraries obtainable; but there has been much general interest in the subject, and private efforts have been organized to extend and improve school libraries.

School libraries for pupils and their families are also found in Sweden, Switzerland, and Belgium.

*Italy* — The government has done nothing for school libraries, but at a library conference in Milan in 1906 it was reported that a national society had been organized with headquarters in Ferrara to promote the establishment of school libraries. Through the efforts of the society the schools of Ferrara and Leghorn had been provided with libraries, and the movement was extending to Pisa, Turin, San Remo, Florence, and elsewhere. The society is doing much, but it cannot take the place of state action, and until that is forthcoming Italy will be far behind its neighbors.

*Spain* — School libraries were created in Spain by government decree in 1869. In 1878 the government purchased 100,000 volumes for distribution to school libraries, but it seemed to consider the work done for all time, as no provision was made for subsequent additions.

J. A. R.

**Pedagogical Libraries** -- Pedagogical libraries in the United States have developed in connection with national, state, and city bureaus of education, state and city libraries, universities, and normal schools.

The U. S. Bureau of Education at Washington, D. C., established in 1867, has collected a pedagogical library of more than 100,000 volumes. In certain classes of educational literature, such as state and city school reports, laws, etc., catalogues and reports of universities, colleges, and schools, files of educational periodicals, and transactions of educational associations, the library is probably the most complete in the country. It has also a large collection of school and college textbooks. While primarily a library for the use of the bureau staff, it is designed to serve also as a central reference and circulating library for educators throughout the country. Books may be borrowed as interlibrary loans, or upon the guarantee of a responsible school official, or of a personal deposit, and are transmitted to the borrower free of charge. The library also supplies bibliographical information on educational subjects through its printed publications and correspondence. Its most significant publications are the *Monthly Record of Current Educational Publications* (No 1, Jan. 15, 1912),

cumulated in the annual *Bibliography of Education*, which now covers the period since 1907, and *A Teacher's Professional Library Classified List of 100 titles* (Washington, 1909). Upon request the library also supplies lists of books and magazine articles on special educational questions. The bibliographical equipment of the library consists of a union catalogue of educational literature in the government libraries at Washington in card form, an extensive card index to the contents of current official reports, society publications, and periodicals relating to education, and a file of reference lists in typewritten manuscript form (W D Johnston. The Library of the Bureau of Education. *Educational Review*, Vol. XXXVI, pp. 452-457, December, 1908. E D Greenman. The bibliographic work of the U S Bureau of Education. *Library Journal*, Vol. XXXVI, pp. 180-181, April, 1911.)

The state pedagogical libraries are identified with either the state department of education, the state library, or the state university. Those of the first class are ordinarily mere office libraries, but two significant exceptions may be noted, that of the New York Department of Instruction, established in 1895, the purpose of which was the circulation of professional and related literature among school officials and teachers throughout the state, and that of the Rhode Island Department of Education, which sought instead to promote the establishment of local collections and with this in view published a periodical *Library Bulletin* (1908).

The New York Education Department library was in 1904 transferred to the state library. In other states, too, the facilities of a general library for the care and distribution of books have led to the development of a pedagogical department of the state library and the circulation of traveling libraries for teachers either by the state library or state library commission. The state universities on the other hand have superior resources for the bibliographical work pertaining to such service.

In California (1889) and New Jersey (1891) county libraries for teachers were established. In each case, however, the tendency has been to merge this special service with the general, and especially to make use of the library resources and equipment of the largest county town.

The first city to establish a pedagogical library was Philadelphia. This library, founded in 1883 upon the accession of Dr. James MacAlister to the office of superintendent of schools, published a catalogue of its collections in 1887, and again in 1907 (525 pp.). This library still remains distinct from the public library service of the city; but in most other cities, as in most states, the special library service has either been transferred to the general library or in some measure made a part of it. In Cleveland, for example, the board of education published in 1892 *Courses of professional reading for teachers and catalogue of pedagogical and refer-*

*ence books of the Free Public Library*. In Providence, on the other hand, it was the public library which first published a catalogue of local collections of pedagogical literature, issuing first a list of books in its own collections (*Monthly Bulletin*, May, 1897), and a year later a catalogue of the public school library at the office of the superintendent of schools. The only other local bibliographical work of significance for teachers is that done by public libraries, examples of which are the *List of textbooks in the Boston Public Library*, *Monthly Bulletin*, September, 1900, and the *Check list of works relating to the schools and to the educational history of the city of New York in the New York Public Library*, published in its *Bulletin* for June, 1901.

Of university pedagogical libraries the earliest and the largest is that of Teachers College, Columbia University. This library, established in 1888, was in 1899 coordinated with the other libraries of the university, and in 1901 a catalogue entitled *Books on Education in the Libraries of Columbia University* (435 pp.) was published. The library now numbers 87,236 volumes and pamphlets, of which 65,336 relate to education. The latter are distributed as follows: history of education, including documents, 15,784; higher education, 21,807; secondary education, 5,472; elementary education, 1,104; training of teachers, 2,734; textbooks, 6,501; other classes, 11,336.

The libraries reported by 185 public normal schools in 1910 contained 1,331,705 volumes, an average of 7,198 volumes each. The largest library, that of the Indiana state normal school, Terre Haute, contained 50,000 volumes. Fifty-seven private normal schools reported 189,823 volumes, an average of 3,330 volumes each.

The principal pedagogical libraries in other countries are the *Pädagogische Central-Bibliothek (Comenius-Stiftung)*, Leipzig, 152,216 volumes and pamphlets (*Katalog der pädagogischen Central-Bibliothek*, 2te Aufl. 1892-1897, 2 v.), the library of the *Musée Pédagogique*, Paris, 76,000 volumes (Catalogue, 1886-1889, 3 v.), and the library of the English Board of Education (25,000 volumes). ### LIBRARY CLASSIFICATION OF EDUCATIONAL PUBLICATIONS —

The system of classification of books on education commonly used in public and in some university and college libraries is the Dewey Decimal System. This classification is as follows:

#### 370 EDUCATION

- 1 Theory of education Meaning Aim
- 109 History of educational theory
- 15 Psychology applied to education
- 3 Dictionaries Cyclopedias
- 4 Essays Addresses
- 5 Periodicals
- 6 Organizations Conventions
- 7 Study of education Institutions and organizations for training teachers
- 71 Teachers' meetings
- 72 Teachers' institutes
- 73 Normal schools
- 74 Educational museums
- 9 History, description
- 92 Educational biography
- 93 99 History of education in special countries

#### 371 TEACHERS METHODS DISCIPLINE

- 1 Teachers Teaching personnel Professors, masters, instructors
- 11 Qualifications Personality
- 13 Examination Certificates Certified teachers Licenses
- 14 Appointment Organization of teaching force
- 15 Professional status
- 16 Salary and promotion Compensation Amount of service
- 161 Salary
- 165 Promotion Advance in rank
- 2 School organization School records
- 21 Admission Enrolment Matriculation
- 212 Grammar or intermediate school admission standards
- 213 High school standards
- 214 College standards
- 23 Terms Vacations Holidays Breaking up
- 25 Classes Grades
- 253 Length of school courses, e g year course
- 27 Examinations oral, written Cramming
- 28 Promotions Degradation
- 3 Methods of instruction
- 32 Textbooks Recitations
- 38 Laboratory work
- 4 Systems of education
- 421 Educational value
- 43 Military organization Military instruction
- 5 Government Discipline Authority
- 52 Attendance Truancy Tardiness Absences
- 53 Rewards Prizes Favors Approbation

## LIBRARY CLASSIFICATION

- 54 Punishment Disciplinary penalties
- 6 School premises and equipment
- 62 Buildings
- 623 Laboratories Observatory Machine shop
- 624 Gymnasium
- 63 Furnishing and decoration
- 631 Furniture
- 64 Libraries
- 648 Professional and technical school libraries
- 65 Museums character and functions
- 66 Scientific apparatus, laboratory equipment and supplies
- 7 School hygiene
- 71 Health of students Overstudy Fatigue
- 712 Medical inspection
- 716 School meals
- 73 Care of body Gymnastics Calisthenics
- 732 Gymnastics Calisthenics
- 74 Recreations Games, etc Athletics Diversions
- 8 Student life and customs
- 87 Student houses Lodgings Dormitories
- 9 Education of special classes
- 91 Physically defective
- 911 Blind
- 912 Deaf
- 913 Blind-deaf
- 92 Physically defective
- 93 Morally defective Delinquents
- 94 Other abnormal classes
- 945 Exceptionals
- 947 Dependents
- 974 Freedmen Negroes
- 975 Indians

#### 372 ELEMENTARY EDUCATION

- 2 Kindergarten
- 3 Observing powers Object teaching Science
- 4 Reading Alphabet Phonics and word methods
- 5 Elementary writing and manual work
- 6 Elementary grammar Language lessons
- 7 Elementary Arithmetic
- 8 Other studies

#### 373 SECONDARY ACADEMIC PREPARATORY

- 374 HOME EDUCATION SELF-EDUCATION AND CULTURE
- 4 Correspondence teaching Manuscript aids
- 5 Lectures
- 6 Extension courses Lecture study
- 8 Continuation schools

#### 375 CURRICULUM

#### 376 EDUCATION OF WOMEN

- 6 Higher education of women
- 7 Coeducation Segregation Separation
- 8 Colleges for women
- 9 Special countries and schools history, reports, etc

#### 377 RELIGIOUS, ETHICAL AND SECULAR EDUCATION

- 1 Religious instruction Bible in public schools
- 2 Ethical education
- 8 Church and education
- 9 Non-Christian religions and education

#### 378 COLLEGES AND UNIVERSITIES

- 05 Academic periodicals
- 06 General college associations
- 1 Organization Government Location Scope, field
- 2 Academic degrees and costume College colors
- 3 Endowment of research Fellowships Scholarships Student aid

## LIBRARY CLASSIFICATION

- .4-98 Special countries and colleges History, reports, etc
- .99 Professional, technical and other special schools
- 379 PUBLIC SCHOOLS RELATION OF STATE TO EDUCATION
  - 1 Public school system
  - .13 Local support
  - .14 School laws and regulations School age
  - .15 School supervision and control national, state and local Centralization
  - .16 Public colleges and universities national, state and local
  - 17 Secondary schools
  - 171 High schools Academies
  - 18 Primary schools Kindergartens
  - 19 Evening schools
  - 2 Illiteracy Instruction of illiterates

The Library of Congress has recently devised a scheme of classification which is now used by the Bureau of Education and other governmental departments, as well as in some other public libraries; and, because of the exchange of index cards inaugurated by the Library of Congress, is apt to be used in many additional libraries. This scheme alone occupies a pamphlet of 168 pages. The outline of this scheme is as follows

- L- General
  - 11-97 Periodicals, Societies
  - 101 Yearbooks
  - 106 Congresses
  - 111-791 Documents. Reports
  - 797-898 Exhibitions Museums
  - 901-981 Directories
- LA5-LB15 Encyclopedias
- LA-History and description
  - 11-13 General
  - 31 Ancient history
  - 96 Mediaeval history
  - 106 Renaissance period and early modern
  - 126 Modern history
  - 205 United States
    - 212 Primary or elementary education
    - 222 Secondary education
    - 226 Higher or university education
- LB- { Theory of education
  - { Principles and practice of teaching
    - 1025 General
    - 1051 Educational psychology
    - 1115 Child study
